Library of Congress Cataloging-in-Publication Data

Names: Khosrow-Pour, Mehdi, 1951- editor.

Title: Encyclopedia of information science and technology / Mehdi

Khosrow-Pour, editor.

Description: Fourth edition. | Hershey, PA : Information Science Reference,

[2018] | Includes bibliographical references and index.

Identifiers: LCCN 2017000834 | ISBN 9781522522553 (set : hardcover) | ISBN

9781522522560 (ebook)

Subjects: LCSH: Information science--Encyclopedias. | Information
technology--Encyclopedias.

Classification: LCC Z1006 .E566 2018 | DDC 020.3--dc23 LC record available at <https://lccn.loc.gov/2017000834>

British Cataloguing in Publication Data

A Cataloguing in Publication record for this book is available from the British Library.

All work contributed to this book is new, previously-unpublished material. The views expressed in this book are those of the authors, but not necessarily of the publisher.

For electronic access to this publication, please contact: eresources@igi-global.com.

This book is dedicated to the memory of my late father for the love and care that he always displayed for his family, and for teaching me the importance of humanitarianism. Also, to my wife, Olga, and our son, Darius, for filling my life with so much love, joy, and happiness.

Silvana de Rosa, Annamaria / Sapienza University of Rome, Italy.....	4038,4064,4404,5237,7014,7044
Simões, Jorge / ISPGaya, Portugal.....	800
Sims, Cynthia M. / Clemson University, USA	4326
Singh, Harwinder / Guru Nanak Dev Engineering College, India.....	587
Singh, Indu / Griffith University, Australia.....	5853
Singh, Kuldeep / Thapar University, India.....	6106
Singh, R. Arvind / Kumaraguru College of Technology (KCT), India.....	431
Singh, Shailendra / PEC University of Technology, India	477
Siu, Kin Wai Michael / The Hong Kong Polytechnic University, Hong Kong	7382
Skarmeta, Antonio F. / University of Murcia, Spain	2749
Skoll, Geoffrey / SUNY at Buffalo, USA	3637
Skoumpopoulou, Dimitra / Northumbria University, UK	1605
Slini, Theodora / Aristotle University of Thessaloniki, Greece	3371
Šmahel, David / Masaryk University – Brno, Czech Republic	4223
Smith, Alan D. / Robert Morris University, USA.....	4837,5273,5476,5516,5570,5595,5918,5981,6094
Smith, Craig / Kyoto University of Foreign Studies, Japan.....	3850
Smith, Pete / University of Aberdeen, UK.....	7815
Smith, Peter A. / University of Central Florida, USA	3327
Smith-Ditizio, Amber A. / Texas Woman's University, USA.....	4837,5273,5570,5595,5918,5981,6094
Sohrabzadeh, Sara / Tehran University of Medical Science, Iran	4436
Sokolov, Alexander / National Research University Higher School of Economics, Russia	4704
Sokouti, Babak / Tabriz University of Medical Sciences, Iran.....	1676
Sokouti, Massoud / Mashhad University of Medical Sciences, Iran.....	1676
Soltani, Pooya / University of Porto, Portugal.....	7358
Šoltés, Michal / Technical University of Košice, Slovakia	5841
Sonnenberg, Christian / Florida Institute of Technology, USA.....	3516
Soomarah, Garry / University of Trinidad and Tobago, Trinidad and Tobago	2532
Soriano, Juan Vicente Izquierdo / La Ribera University Hospital, Spain.....	5787
Sotiriadis, Marios D. / University of South Africa (UNISA), South Africa	4088
Spaananburg, Lambert / Comoray AB, Sweden.....	6114
Spallone, Roberta / Politecnico di Torino, Italy.....	973,5213,7856
Speed, Chris / University of Edinburgh, UK	6695
Spenser, Karin / Nottingham Trent University, UK.....	4168
Spiegel, Thais / Rio de Janeiro State University, Brazil	2076
Spires, Hiller A. / North Carolina State University, USA.....	2235
Spring, Kristian J. / Brigham Young University, USA.....	1487
Sreedhar, G. / Rashtriya Sanskrit Vidyapeetha (Deemed University), India.....	8006

Srinivasan, Srividhya / <i>University of Madras, India</i>	77
Stancu, Stelian / <i>Bucharest University of Economic Studies, Romania</i>	5158,6579
Starrett, David / <i>Columbia College, USA</i>	1451
Stasolla, Fabrizio / <i>University of Bari, Italy</i>	287
Stavrianos, Athanasios T. / <i>2nd Technical Vocational School of Xanthi, Greece</i>	2651
Stefanovic, Nenad / <i>University of Kragujevac, Serbia</i>	5398,5538
Steinfeld, Joshua M. / <i>Old Dominion University, USA</i>	6710
Steri, Gary / <i>European Commission – Joint Research Centre, Italy</i>	6136
Stewart, Craig A. / <i>Indiana University, USA</i>	1063
Steyn, Gert / <i>Kimberley Hospital Complex, South Africa</i>	6147
Stojanov, Zeljko / <i>University of Novi Sad, Serbia</i>	7514
Suaste, Ernesto / <i>Cinvestav-IPN, Mexico</i>	3794
Surmen, Hasan Kemal / <i>Istanbul University, Turkey</i>	298
Susanto, Heru / <i>Indonesian Institute of Sciences, Indonesia & Tunghai University, Taiwan</i>	7369
Svitek, Miroslav / <i>Czech Technical University in Prague, Czech Republic</i>	4391
Swaid, Samar I. / <i>Philander Smith College, USA</i>	8066
Swanson, Karen / <i>Mercer University, USA</i>	1432
Swanson, Pete / <i>Georgia State University, USA</i>	7682
Switzer, Jamie S. / <i>Colorado State University, USA</i>	2121
Switzer, Ralph V. / <i>Colorado State University, USA</i>	2121
Sylaïou, Stella / <i>Aristotle University of Thessaloniki, Greece</i>	7002
Syropoulos, Apostolos / <i>Greek Molecular Computing Group, Greece</i>	2337,2651
Szczepański, Zbigniew / <i>Kazimierz Wielki University, Poland</i>	521
Szeto, Kimmy / <i>Baruch College, City University of New York, USA</i>	6447
Szopa, Anna / <i>Jagiellonian University, Poland</i>	563
T, Tamilarasi / <i>VIT University, India</i>	7503
T., Santhanamery / <i>Universiti Teknologi MARA, Malaysia</i>	831
Tabrizi, Aydin / <i>University of Kansas, USA</i>	983
Tadj, Lotfi / <i>Fairleigh Dickinson University, Canada</i>	1570
Taieb, Basma / <i>University of Cergy Pontoise, France</i>	6070
Taiwo, Ayankunle A. / <i>Texas A&M University – Commerce, USA</i>	3654
Tam, June Poh Kim / <i>Universiti Sains Malaysia, Malaysia</i>	5357
Tambo, Torben / <i>Aarhus University, Denmark</i>	2920
Tan, Amanda C. / <i>University of Central Florida, USA</i>	995
Tani, Kawtar / <i>UCOL, New Zealand</i>	3194
Tannous, Katia / <i>University of Campinas, Brazil</i>	1331
Tazhina, Gainiya / <i>University of International Business, Kazakhstan</i>	5626
Tchangani, Ayeley P. / <i>Université Fédérale Toulouse Midi-Pyrénées, France</i>	7282
Tech, Deb / <i>Dakota State University, USA</i>	3861
Tecpoyotl-Torres, Margarita / <i>Universidad Autónoma del Estado de Morelos, Mexico</i>	2897
Teik, Cheah Cheng / <i>Universiti Sains Malaysia, Malaysia</i>	5422
Teixeira, Leonor / <i>University of Aveiro, Portugal</i>	888,3963
Terras, Melody M. / <i>University of the West of Scotland, UK</i>	6398
Teshome, Assefa K. / <i>Victoria University, Australia</i>	6319
Thakare, Vaishali Ravindra / <i>VIT University, India</i>	1667
Thakur, R. S. / <i>Maulana Azad National Institute of Technology, India</i>	1376

Thompson, Nik / Curtin University, Australia	4124,7481
Tirado-Morueta, Ramon / University of Huelva, Spain.....	3976
Titova, Svetlana / Far Eastern Federal University, Russia	5116
Tiwari, Vivek / International Institute of Information Technology Naya Raipur, India.....	1376
Tobin, Maryann Tatum / University of Miami, USA.....	1508
Tomaiuolo, Michele / University of Parma., Italy	2392,6950
Tommassel, Antonela / ISISTAN, UNICEN-CONICET, Argentina	6658
Torkul, Orhan / Sakarya University, Turkey	2200
Torres-Ruiz, Miguel Jesus / Instituto Politécnico Nacional, Mexico	6973
Tounekti, Oussama / University of Murcia, Spain	2749
Trad, Antoine / Institute of Business and Information Systems Transformation Management, Switzerland	620,636,5607
Tran, Ben / Alliant International University, USA.....	277,671,3173,3260,6756
Tran, Thomas / University of Ottawa, Canada	1757
Traxler, John / University of Wolverhampton, UK	6347
Tremblay, Diane-Gabrielle / University of Quebec, Canada	5027
Tripathy, B. K. / VIT University, India	1835,3226,4528
Tsalighopoulos, Miltiadis / Aristotle University of Thessaloniki, Greece.....	5886
Tsubota, Yasushi / Kyoto Institute of Technology, Japan	3850
Tüfekci, Ashhan / Gazi University, Turkey	6789
Turel, Vehbi / The University of Bingöl, Turkey	2357
Turgay, Safiye / Sakarya University, Turkey.....	2200
Turgay, Tahsin / Sakarya University, Turkey	2200
Tzanis, George / Aristotle University of Thessaloniki, Greece.....	1984
Ulloa, Juan Carlos Solís / Instituto Tecnológico Superior de Cintalapa, Mexico	1277
Umair, Sajid / National University of Sciences and Technology (NUST), Pakistan	5169
Umukoro, Immanuel Ovemeso / Pan-Atlantic University, Nigeria	2724
Ursyn, Anna / University of Northern Colorado, USA	5103
Usat, Selisa / Universiti Teknologi Malaysia, Malaysia.....	7088
Uysal, Tugba Ucma / Mugla Sıtkı Kocman University, Turkey	5737
V., Sriharsha K. / National Institute of Technology Trichy, India	212
Vagelatos, Aristides / CTI&P, Greece	7765
Vagnoli, Laura / Meyer Children's Hospital of Florence, Italy	5955
Van Zyl, D. H. / University of Pretoria, South Africa	777
Vargas-Bernal, Rafael / Instituto Tecnológico Superior de Irapuato, Mexico	2673,2897
Vaterlaus, J. Mitchell / Montana State University, USA.....	7097
Vega-Barbas, Mario / KTH-Royal Institute of Technology, Sweden & ESNE-Universidad Camilo José Cela, Spain	7754
Veglis, Andreas A. / Aristotle University of Thessaloniki, Greece	1196,6476,8046
Velikovskiy, J. T. / University of Newcastle, Australia	4666
Verelst, Jan / University of Antwerp, Belgium.....	5317
Vergara, Luis / Universitat Politècnica de València, Spain	4937
Verma, Anil Kumar / Thapar University, India.....	6106
Vernier, Marco / University of Udine, Italy.....	2064,6195
Verteramo, Saverino / University of Calabria, Italy	7805
Vestias, Mário Pereira / Instituto Politécnico de Lisboa, Portugal	4018,4549,4607

Véstias, Mário Pereira / Instituto Politecnico de Lisboa, Portugal	6307
Vettraino, Laura / Learning Community, Italy	1559
Vilas-Boas, João Paulo / University of Porto, Portugal	7358
Vinzuda, Vipul / National Institute of Design Gandhinagar, India	1260
Viswanathan, Revathi / B. S. Abdur Rahman University, India	7635
Vondrackova, Petra / Charles University in Prague, Czech Republic	4223
Vong, Yunny Meas / Centro de Investigación y Desarrollo Tecnológico en Electroquímica, Mexico	1277
Vorndran, Brittany A. / Seton Hall University, USA.....	5810
Voskoglou, Michael / Graduate Technological Educational Institute (T.E.I.), Greece	3215
Voß, Stefan D. / University of Hamburg, Germany	601
Walczak, Steven / University of South Florida, USA	98,120
Wang, Jingying / University of Chinese Academy of Sciences, China	132
Wang, John / Montclair State University, USA	5388
Wang, Shun-Yung Kevin / University of South Florida – St. Petersburg, USA.....	1656
Wang, Ye / Zhejiang Gongshang University, China	7588
Wani, Zahid Ashraf / University of Kashmir, India.....	4535,5262,6739
Warwick, Kevin / Coventry University, UK	251
Wasim, Muhammad / Usman Institute of Technology, Pakistan	166
Wassan, Jyotsna Talreja / University of Delhi, India	326
Weaver, Kari D. / University of South Carolina – Aiken, USA	7292
Weckman, Gary R. / Ohio University, USA	6642
Weintraub, Eli / Afeka Tel Aviv College of Engineering, Israel.....	1627
Weiss, Andrew Philip / California State University – Northridge, USA.....	5226
Wellman, Barry / NetLab Network, Canada	7057
Wernert, Eric / Indiana University, USA	1063
Westerlund, Mika / Carleton University, Canada	1684
White, Jonathan R. / Höskolan Dalarna, Sweden	1217
Wiafe, Isaac / Ghana Institute of Management and Public Administration, Ghana	7785
Wickramasinghe, Nilmini / Epworth HealthCare, Australia & Deakin University, Australia	3725,6806
Widiyanesti, Sri / Telkom University, Indonesia	5550
Wierzchon, Slawomir T. / Polish Academy of Sciences, Poland	1962
Wilkins-Diehr, Nancy / San Diego Supercomputer Center, USA	1063
Williams, Anne-Evan K. / Billings Middle School, USA	5183
Williams, Idongesit / Aalborg University, Denmark	3549
Williams, James / University of Pittsburgh, USA.....	2707
Wimmer, Hayden / Georgia Southern University, USA.....	1
Winter, Jenifer Sunrise / University of Hawaii at Manoa, USA.....	4951
Wodczak, Michal / Samsung Electronics, Poland.....	6499
Wolf, Frank / CSSTA L3C, USA	6813
Wong, Yi Lin / The Hong Kong Polytechnic University, Hong Kong.....	7382
Wood, Lincoln C. / University of Otago, New Zealand & Curtin University, Australia	5335
Wooldridge, Deborah G. / Bowling Green State University, USA.....	3930
Worthington, Debra L. / Auburn University, USA	6985
Wright, Jorja / University of Charleston, USA.....	7898

Wright, Michelle F. / <i>Masaryk University, Czech Republic</i>	1723,7077
Wulansari, Puspita / <i>Telkom University, Indonesia</i>	5327
Xafopoulos, Alexandros / <i>University College London, UK</i>	6336
Xiaojun (Jenny) Yuan / <i>University of Albany, USA</i>	3745
Xu, Henry / <i>The University of Queensland, Australia</i>	5433
Yadav, Aman / <i>Michigan State University, USA</i>	2292
Yahya, Fadwa / <i>University of Sfax, Tunisia</i>	765
Yang, Hung-Jen / <i>National Kaohsiung Normal University, Taiwan</i>	6057
Yang, Yuqi / <i>University of Windsor, Canada</i>	2314
Yasuda, Gen'ichi / <i>Nagasaki Institute of Applied Science, Japan</i>	6836,7435
Yengin, İlker / <i>A*STAR, Institute of High Performance Computing, Singapore</i>	7168
Yeomans, Julian Scott / <i>York University, Canada</i>	2178
Yfantis, Vasileios / <i>Ionian University, Greece</i>	1033
Yilmaz, Rahime / <i>Istanbul University, Turkey</i>	7470
Young, Richard A. / <i>Driving Safety Consulting, LLC, USA</i>	5992
Young, William A. / <i>Ohio University, USA</i>	6642
Younis, Eman / <i>Minia University, Egypt</i>	8023
Yu, Ligu / <i>Indiana University – South Bend, USA</i>	2739,7116
Yücer, Emre / <i>Erzincan University, Turkey</i>	7831
Yuhua, Fu / <i>CNOOC Research Institute, China</i>	4399
Yusuf, Sarina / <i>Universiti Putra Malaysia, Malaysia</i>	1704,2761
Zaeri, Fahimeh / <i>Auckland University of Technology, New Zealand</i>	539
Zainab, Tazeem / <i>University of Kashmir, India</i>	5262,6739
Zaitsev, Dmitry A. / <i>International Humanitarian University, Ukraine</i>	7731
Zeinali, Ali Akbar / <i>Universiti Sains Malaysia, Malaysia</i>	5136
Zhang, Xinxin / <i>University of Alberta, Canada</i>	2369
Zhang, Yu-Jin / <i>Tsinghua University, China</i>	1308,1319,1344
Zhao, Wenbing / <i>Cleveland State University, USA</i>	1091,1238,1647,3056,4927,5876,5941,8056
Zhou, Chunfang / <i>Aalborg University, Denmark</i>	4178
Zhu, Changye / <i>University of Chinese Academy of Sciences, China</i>	132
Zhu, Tingshao / <i>University of Chinese Academy of Sciences, China</i>	132
Zhu, W. K. / <i>The University of Hong Kong, Hong Kong</i>	505
Zunino, Alejandro / <i>ISISTAN, UNICEN-CONICET, Argentina</i>	6658
Zurloni, Valentino / <i>Università di Milano-Bicocca, Italy</i>	6223
Zykov, Sergey V. / <i>National Research University Higher School of Economics, Russia</i>	1396

Table of Contents by Volume

Preface	clxii
Guide to the Encyclopedia of Information Science and Technology, Fourth Edition	clxviii
Acknowledgment	clxx
About the Editor	clxxi

Volume I **(A - BU)**

Category: Accounting and Finance

Applying Artificial Intelligence to Financial Investing.....	1
<i>Hayden Wimmer, Georgia Southern University, USA</i>	
<i>Roy Rada, University of Maryland – Baltimore County, USA</i>	
Distributed Parameter Systems Control and Its Applications to Financial Engineering	15
<i>Gerasimos Rigatos, Industrial Systems Institute, Greece</i>	
<i>Pierluigi Siano, University of Salerno, Italy</i>	
Does Inter-Bank Investments Restraints Financing Performance of Islamic Banks?.....	36
<i>Mohammad Taqiuddin Mohamad, University of Malaya, Malaysia</i>	
<i>Munazza Saeed, University of Malaya, Malaysia</i>	
An Extension to the Delone and Mclean Information Systems Success Model and Validation in the Internet Banking Context	49
<i>Veeraraghavan Jagannathan, National Institute of Technology, India</i>	
<i>Senthilarasu Balasubramanian, National Institute of Technology, India</i>	
<i>Thamaraiselvan Natarajan, National Institute of Technology, India</i>	
Impact of Business Groups on Payout Policy in India.....	61
<i>Ahana Bose, Indian Institute of Management Calcutta, India</i>	

Noise Trader.....	71
<i>Po-Keng Cheng, State University of New York, Stony Brook University, USA</i>	
Safeguarding of ATM	77
<i>Srividhya Srinivasan, University of Madras, India</i>	
<i>Priya Krishnamoorthy, SASTRA University, India</i>	
<i>Raghuraman Koteeswaran, SASTRA University, India</i>	

Category: Artificial Intelligence

Artificial Ethics.....	88
<i>Laura L. Pană, Polytechnic University of Bucharest, Romania</i>	
Artificial Intelligence	98
<i>Steven Walczak, University of South Florida, USA</i>	
Artificial Intelligence Review	106
<i>Amal Kilani, University of Gabes Tunisia, Tunisia</i>	
<i>Ahmed Ben Hamida, University of Sfax, Tunisia</i>	
<i>Habib Hamam, University of Moncton, Canada</i>	
Artificial Neural Networks.....	120
<i>Steven Walczak, University of South Florida, USA</i>	
Automatic Emotion Recognition Based on Non-Contact Gaits Information.....	132
<i>Jingying Wang, University of Chinese Academy of Sciences, China</i>	
<i>Baobin Li, University of Chinese Academy of Sciences, China</i>	
<i>Changye Zhu, University of Chinese Academy of Sciences, China</i>	
<i>Shun Li, University of Chinese Academy of Sciences, China</i>	
<i>Tingshao Zhu, University of Chinese Academy of Sciences, China</i>	
Board Games AI	144
<i>Tad Gonsalves, Sophia University, Japan</i>	
Computational Intelligence Approaches to Computational Aesthetics	156
<i>Erandi Lakshika, University of New South Wales, Australia</i>	
<i>Michael Barlow, University of New South Wales, Australia</i>	
Dotted Raster-Stereography	166
<i>Muhammad Wasim, Usman Institute of Technology, Pakistan</i>	
<i>Fauzan Saeed, Usman Institute of Technology, Pakistan</i>	
<i>Abdul Aziz, Usman Institute of Technology, Pakistan</i>	
<i>Adnan Ahmed Siddiqui, Hamdard University, Pakistan</i>	
Hybrid Computational Intelligence and the Basic Concepts and Recent Advances.....	180
<i>Georgios Dounias, University of the Aegean, Greece</i>	

Incremental Approach to Classification Learning	191
<i>Xenia Alexandre Naidenova, Research Centre of Military Medical Academy – Saint Petersburg, Russia</i>	
Machine Dreaming.....	202
<i>James Frederic Pagel, University of Colorado School of Medicine, USA</i>	
Moving Object Detection and Tracking Based on the Contour Extraction and Centroid Representation.....	212
<i>Naveenkumar M, National Institute of Technology Trichy, India</i>	
<i>Sriharsha K. V., National Institute of Technology Trichy, India</i>	
<i>Vadivel A, National Institute of Technology Trichy, India</i>	
Semantic Intelligence.....	220
<i>Maria K. Koleva, Institute of Catalysis, Bulgarian Academy of Sciences, Bulgaria</i>	
The Summers and Winters of Artificial Intelligence	229
<i>Tad Gonsalves, Sophia University, Japan</i>	
Swarm Intelligence for Multi-Objective Optimization in Engineering Design	239
<i>Janga Reddy Manne, Indian Institute of Technology Bombay, India</i>	
Trust and Decision Making in Turing’s Imitation Game.....	251
<i>Huma Shah, Coventry University, UK</i>	
<i>Kevin Warwick, Coventry University, UK</i>	

Category: Assistive Technologies

Apps as Assistive Technology	266
<i>Emily C. Bouck, Michigan State University, USA</i>	
<i>Sara M. Flanagan, University of Kentucky, USA</i>	
<i>Missy D. Cosby, Michigan State University, USA</i>	
Assistive Technology and Human Capital for Workforce Diversity.....	277
<i>Ben Tran, Alliant International University, USA</i>	
Assistive Technology for Supporting Communication, Occupation, and Leisure by Children With Severe to Profound Developmental Disabilities	287
<i>Fabrizio Stasolla, University of Bari, Italy</i>	
<i>Viviana Perilli, Lega del Filo d’Oro – Molfetta, Italy</i>	
<i>Adele Boccasini, Lega del Filo d’Oro – Termini Imerese, Italy</i>	
Design, Manufacture, and Selection of Ankle-Foot-Orthoses.....	298
<i>Hasan Kemal Surmen, Istanbul University, Turkey</i>	
<i>Nazif Ekin Akalan, Istanbul University, Turkey</i>	
<i>Yunus Ziya Arslan, Istanbul University, Turkey</i>	

A Disability-Aware Mentality to Information Systems Design and Development.....	314
<i>Julius T. Nganji, University of Ottawa, Canada</i>	

Category: Big Data

Adapting Big Data Ecosystem for Landscape of Real World Applications	326
<i>Jyotsna Talreja Wassan, University of Delhi, India</i>	
Big Data Analysis and Mining.....	338
<i>Carson K. Leung, University of Manitoba, Canada</i>	
Big Data Analytics for Tourism Destinations	349
<i>Wolfram Höpken, University of Applied Sciences Ravensburg-Weingarten, Germany</i>	
<i>Matthias Fuchs, Mid-Sweden University, Sweden</i>	
<i>Maria Lexhagen, Mid-Sweden University, Sweden</i>	
Big Data Time Series Stream Data Segmentation Methods	364
<i>Dima Alberg, Shamoon College of Engineering (SCE), Israel</i>	
Challenges for Big Data Security and Privacy	373
<i>M. Govindarajan, Annamalai University, India</i>	
How Visualisation and Interaction Can Optimize the Cognitive Processes Towards Big Data	381
<i>Antonio Feraco, Fraunhofer IDM@NTU, Singapore</i>	
<i>Marius Erdt, Fraunhofer IDM@NTU, Singapore</i>	
Managing and Visualizing Unstructured Big Data.....	394
<i>Ananda Mitra, Wake Forest University, USA</i>	
Mining Big Data and Streams.....	406
<i>Hoda Ahmed Abdelhafez, Suez Canal University, Egypt</i>	

Category: Bioinformatics

Bioinformatics.....	419
<i>Mark A. Ragan, The University of Queensland, Australia</i>	
Bioinspired Solutions for MEMS Tribology	431
<i>R. Arvind Singh, Kumaraguru College of Technology (KCT), India</i>	
<i>S. Jayalakshmi, Kumaraguru College of Technology (KCT), India</i>	
Building Gene Networks by Analyzing Gene Expression Profiles.....	440
<i>Crescenzo Gallo, University of Foggia, Italy</i>	
Concerns and Challenges of Cloud Platforms for Bioinformatics.....	455
<i>Nicoletta Dessì, Università degli Studi di Cagliari, Italy</i>	
<i>Barbara Pes, Università degli Studi di Cagliari, Italy</i>	

Category: Biology

- GWAS as the Detective to Find Genetic Contribution in Diseases 466
Simanti Bhattacharya, University of Kalyani, India
Amit Das, University of Kalyani, India
- RNA Interference Therapeutics and Human Diseases..... 477
Dolly Sharma, PEC University of Technology, India
Shailendra Singh, PEC University of Technology, India
Trilok Chand, PEC University of Technology, India

Category: Biomedical Engineering

- General Perspectives on Electromyography Signal Features and Classifiers Used for Control of Human Arm Prosthetics..... 492
Faruk Ortes, Istanbul University, Turkey
Derya Karabulut, Halic University, Turkey
Yunus Ziya Arslan, Istanbul University, Turkey
- The Principle and Process of Digital Fabrication of Biomedical Objects 505
S. H. Choi, The University of Hong Kong, Hong Kong
H. H. Cheung, The University of Hong Kong, Hong Kong
W. K. Zhu, The University of Hong Kong, Hong Kong
- Reverse Engineering in Rehabilitation 521
Emilia Mikołajewska, Nicolaus Copernicus University, Poland
Marek Macko, Kazimierz Wielki University, Poland
Zbigniew Szczepański, Kazimierz Wielki University, Poland
Dariusz Mikołajewski, Kazimierz Wielki University, Poland

Category: Business and Organizational Research

- Acceptance of E-Reverse Auction From the Buyer Perspective..... 530
Cigdem Altin Gumussoy, Istanbul Technical University, Turkey
Bilal Gumussoy, Shell and Turcas Petrol Inc., Turkey
- Advanced ICT Methodologies (AIM) in the Construction Industry 539
M. Reza Hosseini, Deakin University, Australia
Saeed Banihashemi, University of Technology Sydney, Australia
Fahimeh Zaeri, Auckland University of Technology, New Zealand
Alireza Adibfar, University of Florida, USA
- Amplifying the Significance of Systems Thinking in Organization..... 551
Mambo Governor Mupepi, Grand Valley State University, USA
Sylvia C. Mupepi, Grand Valley State University, USA
Jaideep Motwani, Grand Valley State University, USA

The Application of Crowdsourced Processes in a Business Environment	563
<i>Katarzyna Kopeć, Tischner European University, Poland</i>	
<i>Anna Szopa, Jagiellonian University, Poland</i>	
Architecture as a Tool to Solve Business Planning Problems	573
<i>James McKee, Independent Researcher, Australia</i>	
Benchmarking Performance Indicators of Indian Rail Freight by DEA Approach	587
<i>Neeraj Bhanot, Dr. B. R. Ambedkar National Institute of Technology Jalandhar, India</i>	
<i>Harwinder Singh, Guru Nanak Dev Engineering College, India</i>	
Bi-Directional Business/IT Alignment	601
<i>Hashim Chunpir, German Climate Computing Centre (DKRZ), Germany</i>	
<i>Frederik Schulte, University of Hamburg, Germany</i>	
<i>Yannick Bartens, University of Hamburg, Germany</i>	
<i>Stefan D. Voß, University of Hamburg, Germany</i>	
Business Sustainability Indices	609
<i>Arunasalam Sambhanthan, Curtin University, Australia</i>	
The Business Transformation Framework, Agile Project and Change Management	620
<i>Antoine Trad, Institute of Business and Information Systems Transformation Management,</i>	
<i>Switzerland</i>	
<i>Damir Kalpić, University of Zagreb, Croatia</i>	
The Business Transformation Framework and Its Business Engineering Law Support for (e)Transactions	636
<i>Antoine Trad, Institute of Business and Information Systems Transformation Management,</i>	
<i>Switzerland</i>	
<i>Damir Kalpić, University of Zagreb, Croatia</i>	
Challenges of Meta Access Control Model Enforcement to an Increased Interoperability	651
<i>Sérgio Luís Guerreiro, University of Lisbon, Portugal</i>	
Cognitive Ergonomics in 2016	662
<i>Ronald John Lofaro, Embry-Riddle Aeronautical University, USA</i>	
Corporate Social Responsibility	671
<i>Ben Tran, Alliant International University, USA</i>	
Digital Transformation Journeys in a Digitized Reality	682
<i>Jurgen Janssens, QSpin, Belgium</i>	
A Framework for Exploring IT-Led Change in Morphing Organizations	694
<i>Sharon A. Cox, Birmingham City University, UK</i>	

How the Crowdsourcing Enhance the Co-Creation Into the Virtual Communities.....	707
<i>Bahri Ammari Nedra, IHEC of Carthage, USA</i>	
Hyper-Sensitivity in Global Virtual Teams	720
<i>Andre Araujo, Texas A&M University, USA</i>	
Lean and Six Sigma Innovation and Design.....	729
<i>Rick Edgeman, Utah State University, USA</i>	
Motivational Factors of Telework.....	740
<i>Arlene J. Nicholas, Salve Regina University, USA</i>	
Organizational Transparency	754
<i>Gustavo de Oliveira Almeida, Federal University of the State of Rio de Janeiro, Brazil</i>	
<i>Claudia Cappelli, Federal University of the State of Rio de Janeiro, Brazil</i>	
<i>Cristiano Maciel, Federal University of Mato Grosso, Brazil</i>	
Social Business Process Modeling.....	765
<i>Fadwa Yahya, University of Sfax, Tunisia</i>	
<i>Khouloud Boukadi, University of Sfax, Tunisia</i>	
<i>Zakaria Maamar, Zayed University, UAE</i>	
<i>Hanène Ben-Abdallah, King Abdulaziz University, Saudi Arabia</i>	
Social Issues in IT Project Teams:.....	777
<i>Awie C. Leonard, University of Pretoria, South Africa</i>	
<i>D. H. Van Zyl, University of Pretoria, South Africa</i>	
Viewpoints on Business Process Models.....	788
<i>Giorgio Bruno, Politecnico di Torino, Italy</i>	

Category: Business Education

Serious Games in Entrepreneurship Education	800
<i>Fernando Almeida, Polytechnic Institute of Gaya, Portugal</i>	
<i>Jorge Simões, ISPGaya, Portugal</i>	

Volume II **(BU - CU)**

Category: Business Information Systems

Architectural Framework for the Implementation of Information Technology Governance in Organisations	810
<i>Thami Batyashe, Cape Peninsula University of Technology, South Africa</i>	
<i>Tiko Iyamu, Cape Peninsula University of Technology, South Africa</i>	

Continuous Assurance and the Use of Technology for Business Compliance	820
<i>Rui Pedro Figueiredo Marques, Universidade de Aveiro, Portugal</i>

Preface

Influencing every facet of business, society, and life worldwide, with speed beyond imagination, the field of information science and technology has without a doubt brought upon a revolution in the way the human population interacts, does business, and governs. As one takes into account the leaps and bounds experienced in information sharing and communication exchange over the last few decades, a truly admirable phenomenon presents itself and clearly shows that the results of this pivotal rising will monumentally impact the way the world thinks, subsists, and evolves.

With a long history of expeditious evolution, the growth and expansion of information technology began during the early 1950s with the main purpose of initiating scientific computing, expanding research, and utilizing the power of computers as a means to support a mass volume of computational tasks in scientific applications and discoveries. Later, during the 1960s and '70s, the use of computer technology was extended to business applications, mostly in accounting and financial areas that involved processing numbers and collecting data in a quantitative sense. As a result, the use of this technology was limited to those who had an expansive knowledge of these systems and had access to computer programming languages. With the evolution of computers and telecommunications in the 1980s, a new information technology was born with a strong focus on the management and dissemination of information by both information providers and users across the globe.

In the early 1990s, the most noticeable advancement in the information technology revolution was the creation of the Internet. During the past two decades, Internet technologies have become the driving force in allowing people worldwide to communicate and exchange information, creating a new virtual, interactive dimension and providing a digital forum for global social connection. In recent years, through the use of Web-enabled technologies, organizations of all types and sizes around the world have managed to utilize these technologies to disseminate and process information with prospective customers, suppliers, students, and governments. Today, the ability to communicate and connect from many locations through personal computers has influenced different people in many different societies. These technologies allow everyone, regardless of their geographic location, to bring the information age to its full realization.

In recent years, the science of understanding the nature of information processing and management, along with the computers and technologies that decipher, disseminate, and manage information, has become known as information science and technology. Technology has profoundly impacted science, business, and society, thus constructing an entity that improves access to the rapidly expanding body of knowledge in almost every discipline. Society fuels this knowledge creation, as it receives, manages, educates, and collects information. The volume and intensity of research in information science and technology have exceeded many other fields of science, and research discoveries have become the impetus behind many emerging tools and applications seen at every organizational level.

Preface

In addressing this need for the representation of evolving information science and technology disciplines in academic literature, the first edition of the *Encyclopedia of Information Science and Technology*, released in early 2005, positioned itself as the first of its kind in reference publications, offering an invaluable source highlighting major breakthroughs, discoveries, and authoritative research results in technological advancements. In providing this compendium of references, definitions, and keywords within this field of pivotal social and organizational movement, the five-volume *Encyclopedia of Information Science and Technology* (First Edition) supplied researchers with a definitive one-stop reference source.

In late 2008, the *Encyclopedia of Information Science and Technology* (Second Edition) followed the first edition with an eight-volume compendium of updated research on crucial topics previously covered in the first edition, as well as an advanced treatment of new developments, technologies, and areas of research in the field of information and communications science. With an expanded number of contributions, the second edition surpassed the first in terms of timeliness, comprehensiveness, and critical acclaim, lauded as an essential reference for any academic library.

With the endeavor of continuing to exhibit the latest research innovations and advances, the third edition of the *Encyclopedia of Information Science and Technology* was comprised of 10 volumes of all new content and uncovered the most current research findings related to technological, organizational, and managerial issues, challenges, trends, and applications of information technologies in modern organizations. The coverage in the third edition of the encyclopedia bridged existing gaps in available references on technology and methodologies with its contribution as a valuable resource of encompassing paradigms shaping the ever-changing research, theory, and discovery of information science and technology.

This brings us to the present, and three years later we are again releasing new materials providing the latest trends and research in this ever-changing field. The selected topics of this encyclopedia provide a balanced representation of concepts and issues from researchers around the world. These researchers were asked to submit proposals describing the topic and scope of their articles. All proposals were carefully reviewed for suitability by the Editor-in-Chief. Upon the receipt of full article submissions, each contribution was forwarded to at least three expert external reviewers on a double-blind peer review basis. Only submissions with strong and favorable reviews were chosen as articles for this edition of the *Encyclopedia of Information Science and Technology*. In some cases, submissions were sent back for several revisions prior to final acceptance. The goal was to assemble the best minds in the information science and technology field from all over the world to contribute articles to this encyclopedia and to apply the highest level of quality in selecting articles for inclusion.

As a result, over 700 new articles were carefully selected for inclusion in this 10-volume encyclopedia based on their presentation of the most comprehensive, innovative, and in-depth coverage of the current concepts, issues, and emerging technologies in the field of information science and technology. The articles included in this edition of the encyclopedia are written by more than 1,400 distinguished scholars and researchers from hundreds of prominent research institutions all over the world. Over 5,000 technical and managerial terms and their definitions have been organized by the authors to enhance the articles, allowing for extensive research into core concepts and ideas. In addition, this 10-volume set offers a thorough reference section with approximately 15,000 sources of additional information for scholars, students, and researchers in the field of information science and technology. Multiple tables of content have been organized to better assist readers in navigating and identifying information. Contents are structured through alphabetical and categorical listings for easy reference.

The topics covered in this all-encompassing publication include some of the most influential areas in the field. One such example is the area of *artificial intelligence* and its current application within organizational spheres: specifically, technologies such as machine learning, computational intelligence, digital ecosystems, neural networks, and adaptive systems. Content coverage such as this will supply audiences with reputable sources for identifying future trends and breakthrough technologies that will directly impact everyday aspects of life, with specific examples being the latest computing and technological advancements in smart homes, as well as the integration of intelligent diagnostics and speech recognition technology in a variety of settings.

A substantial portion of this encyclopedia is dedicated to the latest advancements in business research, management, and technologies. Through the review of *business organizational research* and *business information systems* and their ever-changing state, this encyclopedia analyzes the driving force of globalization, and the effect of these systems on international trade, economics, and capital. Because business information systems are so far-reaching, from the intranet to export tracking and manufacturing intelligence, the research results presented within these articles examine a breadth of review and discussion of methodologies behind these systems and how they are implemented in the field of business.

Cybercrime, cyber bullying, and digital terrorism, a growing discipline fueled by daily reminders in news outlets around the world, is covered in several articles within this encyclopedia. Special attention has been paid to how behavior across all cultures affects all participants, with good and bad effects in our digitally wired world.

Continuously utilized in the evolution of technical applications, the areas of *data mining and databases* are comprehensively covered in a significant number of articles in this edition of the encyclopedia for both the purpose of introduction and advancement. Taking into consideration the growing use of data mining and database management in a number of activities such as Web development and engineering progress, these resources supply readers with authoritative results and a foundation for additional research.

With a considerable effect on the global economy, *electronic business* applications are discussed in this edition of the encyclopedia and offer researchers a credible source of knowledge for understanding the current realms of mobile applications for business functions, social commerce, and virtual enterprises. Seeing the importance of these technology-based management systems, modern electronic business is analyzed as a growing phenomenon of capitalism.

As the world becomes increasingly engaged in online shopping and trade, *electronic commerce* is fully presented in this edition of the encyclopedia as a phenomenon of progressive change. With significant growth since the dot-com explosion of the past two decades, e-commerce is now considered a discipline with significant global implications, particularly on international trade and how goods and currencies are exchanged and services are dealt.

As a contemporary social motivator, *educational technologies* are comprehensively and extensively examined in this edition of the encyclopedia. This is an area of research with philosophical and constructivist reach into all levels of learning. In discussing blended learning, distance education, tools for online learning, advanced pedagogy, virtual learning environments, and computational support for teaching, educational technologies demand further attention in developing reliable research. As a popular area of examination, this encyclopedia lends support to emerging trends in the discipline while supplying a venue for further discussion of terms, themes, and additional implications.

Preface

A new category on *gaming* makes its debut in this fourth edition, and reflects on how pervasive the gaming industry has become, no longer just for entertainment but a very real part of learning. Cognitive effects, theoretical models, game-based designs, and modeling are discussed in this section of the encyclopedia.

Given the worldwide focus on the environment, this edition of the encyclopedia provides tremendous coverage of emerging technologies and applications in the areas of *environmental science and agriculture*. As a growing academic research area, this discipline is supported by many research papers written by prominent international researchers studying the future of maintaining environmental functions and safeguarding the planet.

Global information technology has emerged as an area of study with growing importance as digital communications spread internationally. This edition of the encyclopedia supplies articles that delve into the importance of the global economy, as well as exhibiting regional adaptation, resistance, and adoption of technologies.

Patient monitoring systems, e-health, and cybertherapy are three of the many topics extensively covered in this edition of the encyclopedia by providing a wealth of knowledge related to *health information systems* and their use and implications in modern societies. With new assistive and rehabilitative technologies, medical data storage, and issues of security and privacy, health information systems affect the lives of human beings worldwide. Considering this growth, research results prove invaluable for healthcare administrators and academic disciplines, such as nursing and health management.

As technological demands extend and users multiply, *high-performance computing* seeks to maintain the flow of communication between servers, knowledge workers, and organizations. With much recent advancement in cloud computing and technologies to handle large amounts of data, this edition of the encyclopedia offers researchers a comprehensive convergence of all topics related to cloud computing applications and management.

Considering the human element in making technology the paradigm it is today, this edition of the encyclopedia provides comprehensive coverage of human aspects of technology. With an analysis of end-user behavior, gender differences, and ubiquity of computing, readers will find an extensive amount of research results and analysis to assist in building the literature in an important area of study: *human-computer interaction*.

Following the advancements of the Industrial Revolution, *industrial informatics* is described in this encyclopedia as a bridge between technological progress and the application of manufacturing, transportation, and construction. With growing utilization in enhancing and expediting good production, building, and usage, research results examine the future trends of such technologies and how these applications will incorporate into the daily lives of individuals around the globe.

Taking into account the massive growth in technological utilization for sensitive data, both in personal and organizational functions, *IT security and ethics* as an area of study continues to evolve, expanding securitization and streamlining for the best protection of digital information. In examining such areas as digital forensics, authentication, cryptography, cyber warfare, and trustworthy computing, analysis of IT security and ethics takes prominence as a point of key discussion in this edition of the encyclopedia.

As the result of the current structures of both public and private sector administration, the field of *knowledge management* has been positioned as a concept of both utility and application. Considering the need for quality sources indicating best practices in the management of knowledge workers, IT governance, and information sharing, this encyclopedia supplies readers and researchers with a considerable selection of current themes, terms, and topics relating to the current and future state of knowledge management.

With many library systems implementing digital filing and cataloguing systems, the study of bibliometrics has flourished in the scientific world. With cutting-edge technologies in archiving and classification, preservation, and reformatting, digital *library science and administration* has developed into an intricate branch of information science, and this encyclopedia provides a tremendous coverage of the vast spectrum of this study. As issues such as open access, security, and Internet property rights take center stage, legal aspects of the digitization of information are explored extensively.

Advanced *medical technologies* are incorporated into daily measures to secure and save lives. Medical informatics is explored in this fourth edition encyclopedia through an intricate look at the updates and improvements in this pivotal field. Medical imaging, biosensors, and new nanotechnology modernizations for surgical procedures are a few of the exciting and significant advances in medical technologies. Rehabilitation, disease detection, and mobile medical care are assisted and revamped with advances in hospital machinery and tools.

Mobile devices, wireless systems, sensors, and wearable computing applications are technologies that are shaping communication and public administration. Keeping in mind the spread of the need for reliable means of information transfer, *mobile and wireless computing* is explored in this edition of the encyclopedia as a field of widening pervasiveness. With uses ranging from machine correspondence to business interrelationships, important research findings are effectively exposed and discussed by top researchers in the field.

Whether utilized for entertainment, learning, or public policy, *multimedia technology* as a form of study involves behavioral and practical analysis. This edition of the encyclopedia offers readers a wealth of research coverage addressing many aspects of analysis on topics such as simulation, digital imaging, and hypermedia to best understand how the world is displaying its information for consumers and administrators.

Social networking and computing describes the intersection of social behaviors and computer systems, intricately examining areas such as social networking sites, augmented realities, and online auctions, and their substantial impact on society. Tools such as blogs, Wikis, tags, and podcasts have expanded the user's online researching experience. This edition of the encyclopedia expounds on social informatics and explores emerging technologies and applications such as instant messaging, virtual groups, mailing lists, and forums: just a few of the places that users interact with one another.

For several decades, technological engineers have focused on algorithms, modeling languages, and kernel applications in designing and formatting the machines and automation that the world uses today. Innovative *systems and software engineering* technologies now play a crucial role in the future design and improvement of the ever-changing world of automation. This edition of the encyclopedia provides ample research coverage of the emerging technologies in this area and their vulnerabilities, specifications, quality, and architectures.

As a result of the Internet explosion of the 1990s, *Web technologies* as a field of study has taken the stage as a discipline of ubiquitous importance. With the Web being a single source of infinite information and computing, responding and expanding at exponential rates, this encyclopedia offers researchers a tremendous coverage of emerging innovations in disciplines such as portal technologies, semantic computing, Web 2.0, and service-oriented technologies.

Preface

In closing, the diverse and comprehensive coverage of multiple disciplines of information science and technology in this 10-volume, authoritative encyclopedia are sure to contribute to a better understanding of all topics, research, and discoveries in this evolving field. Furthermore, the contributions included in this publication will be instrumental in the expansion of knowledge in this field. This publication will inspire its readers to further contribute to the current discoveries in this immense field, creating possibilities for further research and discovery into the future of information science and technology and what lies ahead for the knowledge society.

Mehdi Khosrow-Pour, D.B.A.

Editor-in-Chief

Encyclopedia of Information Science and Technology, Fourth Edition

Guide to the Encyclopedia of Information Science and Technology, Fourth Edition

ORGANIZATION

The *Encyclopedia of Information Science and Technology, Fourth Edition* is a 10-volume set comprised of over 700 articles. All articles are divided into categories relevant to their topical coverage. There are 86 different category sections, with each volume containing multiple categories. All category sections are arranged alphabetically across the 10 volumes, beginning with “A” categories and ending with “W” categories. Within each category section, the articles are also arranged in alphabetical order. As each new category is introduced, section dividers represent the transition from one category to the next. Also, in the print version of the encyclopedia, letters for the categories represented in each volume are clearly marked on the side binding of the cover.

To assist with easy navigation, there are two different tables of content compiled at the beginning of each volume. The first represents the “Contents by Volume,” which displays the arrangement of the content in its respective categories, and the second represents the “Contents in Alphabetical Order,” which displays the arrangement of content from A to Z by the articles’ titles.

EACH VOLUME CONTAINS

- A **preface** and **user’s guide**.
- The **Editor-in-Chief’s biography** and **acknowledgment**.
- **Two tables of content** are compiled at the beginning of each volume: “Contents by Volume” and “Contents in Alphabetical Order.”
- **Several authoritative, research-based articles** contributed by thousands of researchers and experts from all over the world.
- A **comprehensive index** supporting the extensive system of cross-references.

EACH ARTICLE INCLUDES

- A brief **introduction to the topic area** describing the general perspective and objectives of the article.
- A **background** providing the broad definitions and discussions of the topic and incorporating the views of others (i.e., a literature review) into the discussion to support, refute, or demonstrate the author's position on the topic.
- Various perspectives examining the **issues, controversies, and problems** as they relate to the theme. Also provided are arguments supporting the position as well as a comparison and contrast with regards to what has been and/or is currently being done as it relates to the article's specific topic and the overall theme of the encyclopedia.
- A discussion of **solutions and recommendations** in dealing with the issues, controversies, or problems presented in the preceding section.
- **Charts, graphs, tables, and formulae** are included as illustrative examples whenever appropriate.
- A discussion of **future research directions**.
- A **conclusion** to discuss the overall coverage of the article and present concluding remarks.
- An extensive **list of references** so that readers can benefit from the sources cited within the text.
- An **additional readings section** consisting of sources that complement the topical coverage within the article.
- A **key terms and definitions section** providing 7-10 terms related to the topic of the article with a clear and concise definition for each term.

Acknowledgment

Editing and completing an authoritative and comprehensive scholarly research publication such as the *Encyclopedia of Information Science and Technology, Fourth Edition* requires tremendous contributions, and a great deal of assistance from large groups of scholars and staff. The primary objective of this encyclopedia is to provide the most up-to-date scholarly coverage of all topics related to information science and technology as it is applied to several discipline areas, such as business, engineering, medicine, education, public administration, computer science, as well as the social sciences and humanities. I am indebted to all the authors for their excellent contributions to this edition of the encyclopedia.

All submitted manuscripts to this 10-volume edition underwent a double-blind peer review process in order to achieve the highest level of quality and accuracy. I am thankful to all the reviewers of this edition for providing their expertise and their rigorous, unbiased assessment of the manuscripts assigned to them on a double-blind basis, as well as the members of the Editorial Advisory Board for their wisdom, guidance, and assistance with various decisions throughout the editorial process.

I would also like to convey my deep appreciation and gratitude to Jan Travers, Director of Intellectual Property and Contracts, for all her tireless efforts assisting me with bringing a publication of this size to fruition, as well as to the Acquisitions, Development, Copy Editing, and Production Divisions of the Editorial Content Department at IGI Global for their valuable assistance in support of this project, especially Chris Shearer, Copy Editing Manager, Christina Henning, Production Editor, Courtney Tychinski, Assistant Managing Editor (Book Development), Mariah Gilbert, Assistant Managing Editor (Acquisitions), and also to Lindsay Wertman, IGI Global's Managing Director. Additionally, I would like to thank the IGI Global Sales and Marketing Department for their endless support in promoting this invaluable reference source.

Thank you to everyone who has provided me immeasurable amounts of knowledge, wisdom, and patience over the last 30 years.

Mehdi Khosrow-Pour, D.B.A.

Editor-in-Chief

Encyclopedia of Information Science and Technology, Fourth Edition

About the Editor

Mehdi Khosrow-Pour, D.B.A., received his Doctorate in Business Administration from the Nova Southeastern University (Florida, USA). Dr. Khosrow-Pour taught undergraduate and graduate information system courses at the Pennsylvania State University – Harrisburg for almost 20 years. He is currently Executive Editor at IGI Global (www.igi-global.com). He also serves as Executive Director of the Information Resources Management Association (IRMA) (www.irma-international.org) and Executive Director of the World Forgotten Children's Foundation (www.world-forgotten-children.org). He is the author/editor of more than 100 books in information technology management. He is also currently the Editor-in-Chief of the *International Journal of Green Computing*, *International Journal of Library and Information Services*, *International Journal of E-Entrepreneurship and Innovation*, and *International Journal of Natural Computing Research*, and is also the founding Editor-in-Chief of the *Information Resources Management Journal*, *Journal of Electronic Commerce in Organizations*, *Journal of Cases on Information Technology*, and the *Journal of Information Technology Research*, and has authored more than 50 articles published in various conference proceedings and scholarly journals.

Accounting and Finance

Applying Artificial Intelligence to Financial Investing

A**Hayden Wimmer***Georgia Southern University, USA***Roy Rada***University of Maryland – Baltimore County, USA*

INTRODUCTION

Artificial intelligence (AI) techniques have long been applied to financial investing scenarios to determine market inefficiencies, criteria for credit scoring, and bankruptcy prediction, to name a few. While there are many subfields to artificial intelligence this work seeks to identify the most commonly applied AI techniques to financial investing as appears in academic literature. Techniques identified in this work include fuzzy systems, swarm intelligence, case-based reasoning, hybrid systems, genetic algorithms, neural networks, and machine learning. AI techniques, such as knowledge-based, machine learning, and natural language processing, are integrated into systems that simultaneously address data identification, asset valuation, and risk management. Frequently, machine learning is applied to technical financial indicators in order to make predictions about the direction of stock prices. Financial investing requires data identification, asset valuation, and risk management. One such example of applying AI techniques to financial investing is the application of knowledge-based techniques for credit risk assessment and machine learning techniques for stock valuation. Future trends will continue to integrate hybrid artificial intelligence techniques into financial investing, portfolio optimization, and risk management. The remainder of this article summarizes key contributions of applying AI to financial investing as appears in the academic literature.

BACKGROUND

What Is Artificial Intelligence?

In the early days of computing, a typical task for a computer program was a numerical computation, such as computing the trajectory of a bullet. In modern days, a typical task for a computer program may involve supporting many people in important decisions backed by a massive database across a global network. As the tasks that computers typically perform have become more complex and more closely intertwined with the daily decisions of people, the behavior of the computer programs increasingly assumes characteristics that people associate with intelligence. When exactly a program earns the label of ‘artificial intelligence’ is unclear. The classic test for whether a program is intelligent is that a person would not be able to distinguish a response from an intelligent program from the response of a person. This famous Turing Test is dependent on factors not easily standardized, such as what person is making the assessment under what conditions.

A range of computer programming techniques that are currently, popularly considered artificial intelligence techniques includes (Rada, 2008):

- Knowledge-based techniques, such as in expert systems.
- Machine learning techniques, such as genetic algorithms and neural networks.

- Sensory or motor techniques, such as natural language processing and image processing.

These methods may apply to investing. For instance, expert systems have been used to predict whether a company will go bankrupt. Neural networks have been used to generate buy and sell decisions on stock exchange indices. Natural language processing programs have been used to analyze corporate news releases and to suggest a buy or sell signal for the corporate stock.

While artificial intelligence (AI) could apply to many areas of investing, much of what happens in computer-supported investing comes from non-AI areas. For instance, computational techniques not considered primarily AI techniques include numerical analyses, operations research, and probabilistic analyses. These non-AI techniques are routinely used in investing.

Investing and Data

The process of investing has 3-stages of:

1. Data Identification,
2. Asset Valuation, and
3. Risk Management.

AI has been most often applied to asset valuation but is also applicable to data identification and risk management.

Two, high-level types of data used in financial investing are technical data and fundamental data. The price of an asset across time is technical data and lends itself to various computations, such as the moving average or the standard deviation (volatility). Fundamental data should support cause-and-effect relationships between an asset and its price. For instance, the quality of management of a company should influence the profitability of a company and thus the price of its stock.

The universe of fundamental data is infinite. Many streams of data that might be relevant, such as corporate earnings or corporate debt, might also

be related to one another. Various non-AI tools, such as linear regression analysis and principal components analysis, might be used in identifying what sets of data are more likely to be useful than what other sets. Such non-AI, computational techniques can be combined with AI techniques in experimenting with various combinations of data and choosing what data to use in asset valuation.

ARTIFICIAL INTELLIGENCE APPLIED TO FINANCIAL INVESTING

AI Trends

A multi-agent architecture for an integrated system that considers data identification, asset valuation, and risk management has been proposed by researchers at Carnegie Mellon University. The system is called WARREN which refers to the first name of the famous investor Warren Buffet (Sycara, Decker, Pannu, Williamson, & Zeng, 1996). The WARREN system design includes components for collecting large amounts of real-time data, both numeric and textual. The data would be pre-processed and then fed to various asset valuation agents that would, in turn, feed their assessments to a portfolio management agent. The portfolio management agent would interact with clients of WARREN. Systems with various features of WARREN are available from commercial vendors and are developed in-house by large investing companies, but more research is needed on how to develop integrated, AI systems that support investing.

Natural language processing systems may include large bodies of domain knowledge and parse free text so as to make inferences about the content of the text. However, such natural language processing systems do not seem as popular in investing applications as much simpler natural language processing techniques. The natural language processing work that has been applied to investing seems to be largely of the sort in which the distribution of word frequencies in a

document is used to characterize the document. In this word-frequency way, Thomas (2003) has shown a potential value to processing news stories to help anticipate stock price changes.

As one can see cycles in the value of financial assets, one can also see cycles in the frequency of publication of articles on certain topics. In the field of artificial intelligence, one might identify, roughly speaking, three phases as follows (Rada, 2008):

1. Machine learning, in what was then called perceptron and self-organizing systems research, was popular from 1955 to 1975,
2. Knowledge-based, multi-agent, or expert systems work was popular from 1975 to 1995, and
3. Machine learning research, now called neural networks or genetic algorithms research, returned to dominate the AI research scene from 1995 to 2013.

When AI research has been applied to investing, the AI technique used has tended to be the technique popular at the time. This leaves unaddressed the question of whether investing is more appropriately addressed with one AI technique or another.

The recent literature is rich with neural network applications to investing, but a new trend is the combining of knowledge-based techniques with neural network and genetic algorithm techniques. For instance, Tsakonas, Dounias, Doumpos, and Zopounidis (2006) use 'logic' neural nets that can be directly understood by people (traditional neural nets are a 'black box' to humans). Genetic programming modifies the architecture of the logic neural net by adding or deleting nodes of the network in a way that preserves the meaning of the neural net to people and to the net itself. Bhattacharyya, Pictet, and Zumbach (2002) have added knowledge-rich constraints to the genetic operators in their application for investing in foreign exchange markets.

A promising research direction is to combine the earlier knowledge-based work on financial accounting with the more recent work on machine learning for stock valuation. For instance, neural logic nets could represent some of the cause-effect knowledge from a bankruptcy system and become part of a learning system for predicting stock prices. Some of the bankruptcy variables are readily available online, such as a company's debt, cash flow, and capital assets.

The financial markets are human markets that evolve over time as opportunities to make profits in this zero-sum game depend on the changing strategies of the opponent. Thus, among other things, what is important in the input may change over time. An AI system should be able to evolve its data selection, asset valuation, and portfolio management components. The future direction for AI in investing is to integrate the three major tools of AI (knowledge-based systems, machine learning, and natural language processing) into a system that simultaneously handles the three stages of investing (data collection, asset valuation, and portfolio management). Such systems will interact with humans so that humans can specify their preferences and make difficult decisions, but in some arenas, such as program trading, these sophisticated AI systems could compete with one another.

Advances in AI and Finance 2009-2013

Artificial intelligence techniques continue to be applied to areas in finance in order to extend human capabilities by surveying large and distributed data sources (Phillips-Wren, 2012). Artificial neural networks (ANNs) continue to be the most popular approach to combining artificial intelligence with finance (Bahrammirzaee, 2010). ANNs have been applied to a variety of issues in the finance domain. One such example is applying ANNs to auditor selection where the process of selecting and appointing an auditing firm is a complex

process which can benefit from the ANN approach (Kirkos, Spathis, & Manolopoulos, 2010). Employing ANNs was found to outperform the standard approach of logistic regression. ANNs are suited to modeling non-linear as well as linear relationships and are well suited to applications in financial, time-series forecasting and can be tailored by customizing the input and hidden neurons of the ANN (Tarsauliya, Kant, & Kala, 2010). Currency exchange rates are another financial time-series where an ANN approach can be effective (Oyewale, 2013).

In addition to ANN techniques, techniques such as nearest neighbor (kNN) have been explored. One such technique combines a kNN approach with technical analysis techniques for stock trading where the method was more profitable than the standard buy and hold technique (Teixeira & de Oliveira, 2010). Support Vector Machines (SVMs) are supervised learning models which are used for data analysis and pattern recognition. SVMs have been applied to a range of finance research with one such being financial distress prediction (Bae, 2012). Besides SVM, fuzzy approaches, or approaches which deal with approximations, have begun to emerge in portfolio selection (Magoč & Modave, 2011).

Evolutionary approaches have been studied, as in (Chi & Hsu, 2012), where a genetic algorithm (GA) was employed in variable selection for determining credit scoring of business firms. The GA was used to augment a bank's internal scoring model and a credit bureau scoring model in order to improve the performance of credit risk management of mortgage accounts. Dividend policy forecasting was also shown to benefit from the introduction of evolutionary computation methods where the introduction of a GA was able to outperform the average prediction accuracy of standard machine learning decision tree classifiers such as CHAID, CART, and C4.5 (Won, Kim, & Bae, 2012). Genetic Algorithms applied to technical trading indicators improve the ability to predict major losses (Kaucic, 2010). Following the theme of technical analysis, Fu, Chung, and

Chung (2013) proposed a 2 step process to technical analysis by first applying a GA to determine the optimal technical indicators and then again to weight the investments of a financial portfolio. The method lowered risk, as measured by the Sharpe ratio, and outperformed the buy and hold method over different market sectors in bullish and bearish market conditions.

While artificial neural networks remain the most popular research stream for applying artificial intelligence techniques to finance (Bahrammirzaee, 2010), hybrid AI approaches are emerging as a viable, however complex, alternative. For example, decision trees have been shown to be effective when combined with logistic regression when applied to financial distress prediction (Chen, 2011). The hybrid approach trend continues by combining decision trees and fuzzy approaches. The high dimensionality and non-stationary variations in stock price make financial trend discovery difficult; therefore, an approach which uses fuzzy logic combined with a decision tree classifier has been shown to be effective when applied to the S&P 500 (Chang, Fan, & Lin, 2011). Genetic algorithms show promise when paired with fuzzy techniques and applied to portfolio selection (Bermúdez, Segura, & Vercher, 2012). While Fuzzy approaches are viable in portfolio selection, extending fuzzy approaches by incorporating swarm convergence techniques provides satisfactory performance when compared with other techniques (Ladyzynski & Grzegorzewski, 2013).

Compared with other independent methods, ANN approaches have demonstrated higher performance as evidenced by (Rafiei, Manzari, & Bostanian, 2011). This makes combining ANN with other AI approaches a natural extension to the research. Combining ANN with Case-Based Reasoning (CBR) was explored by (Chuang & Huang, 2011) and compared to ANN alone and shown to improve accuracy and reduce misclassification errors. Hybrid approaches that pair ANN with Fuzzy systems have also emerged as an extension to ANN alone. One such approach integrates ANN with genetic fuzzy systems and

applies the technique to stock price forecasting (Hadavandi, Shavandi, & Ghanbari, 2010). The method was applied to a subset of stocks in the IT and airline sector and was demonstrated to outperform previous methods of stock price prediction. A similar method of combining ANN and fuzzy systems was examined in (Boyacioglu & Avci, 2010) where the authors concluded the approach of combining ANN and fuzzy systems, namely fuzzy logic, is applicable to emerging markets' stock price prediction. In continuing with stock price prediction, K.-L. Shen (2013) combined ANN and a fuzzy approach to create a Fuzzy-ANN model which was shown to outperform two major market indices from Taiwan from 2008-2011.

LITERATURE TREND 2013-2015

In order to examine trends in the literature, a Google Scholar search on "Artificial Intelligence and Investing" and "Artificial Intelligence and Financial Investing" was performed. The search spanned January 1, 2013 until July 1, 2015. In 2013, the dominant categories of artificial intelligence and financial investing literature can be classified as fuzzy approaches, neural networks, hybrid approaches, and other methods. In 2014, hybrid methods increase in popularity. Hybrid systems are systems which utilize a combination of two or more techniques and/or methods. This increase in hybrid system interest continues into 2015 which concludes this analysis. Machine learning and neural networks are two of the most common methods found in hybrid systems thereby

Table 1. Citation count from google scholar for "artificial intelligence and investing"

Year	Citation Count
2013	1930
2014	1980
2015	1330
2013-2015	5230

Table 2. Citation count from google scholar for "artificial intelligence and financial investing"

Year	Citation Count
2013	7
2014	12
2015	12
2013-2015	26

Table 3. Google scholar sub-field citation count

AI Subfield Citation Count 2013-2015 (Oct)	
Topic	Citation Count
Fuzzy System and Investing	213
Swarm Intelligence and Investing	304
Case Based Reasoning and Investing	394
Hybrid System and Investing	982
Genetic Algorithm and Investing	1930
Neural Network and Investing	2760
Machine Learning and Investing	3360

explaining the high citation count. Most hybrid systems do not specifically mention the term "hybrid" in the article title thereby explaining the lower number of hybrid citations.

Artificial Intelligence and Financial Investing (2013)

Fuzzy approaches were well represented. For example, Svalina, Galzina, Lujčić, and Šimunović (2013) generate a prediction model based on an adaptive neuro-fuzzy inference system to detect the close price of the Croatian Zagreb Stock Exchange. Yunusoglu and Selim (2013) propose a new fuzzy rule expert system that focusses on helping investors with investment decisions. Messaoudi and Rebai (2013) develop a new fuzzy goal programming model, which takes into consideration stochastic and fuzzy uncertainty for real life decision making problems for portfolio selection. Hassan, Ramamohanarao, Kamruzzaman, Rahman, and Hossain (2013) introduce a new adaptive inference system, which generates new fuzzy rules for forecasting

Figure 1. Citation counts of “artificial intelligence and investing” google scholar search from 2013-2015

the nonlinear time series data in stock market which performs better than the standard FIS and the performance of this system indicates that it can predict a number of stock indices including Dow Jones Industrial index, and NASDAQ index. Gradojevic and Gençay (2013) address the trading uncertainty problem by employing fuzzy logic to reduce trading uncertainty.

Neural networks remained a well-represented area of research. de Oliveira, Nobre, and Zárate (2013) use a neural network approach to predict the direction of change in stock price. Korol (2013) apply neural networks to bankruptcy prediction. Birău, Ehsanifar, and Mohammadi (2013) employ neural networks for predicting emerging stock prices. Devadoss and Ligorì (2013) show that neural networks can be an effective tool for predicting closing stock prices. Liu, Dang, and Huang (2013) propose a recurrent neural network with convergence for real time portfolio optimization for portfolio optimization. Özkan (2013) focuses on improving the foreign exchange rate forecast accuracy by using neural networks for forecasting the foreign exchange rates. Dong, Fataliyev, and Wang (2013) utilize Neural Network techniques for forecasting the stock prices. Kumar and Murugan (2013) emphasize the importance of neural networks for stock indices and conducts experiments to analyze the forecasting accuracy. Al-Jumeily, Hussain, and Alaskar (2013) propose

a new technique for predicting change in the large financial data sets used for forecasting the noisy time series data using a Dynamic Self-Organized Multilayer Neural Network based on the Immune algorithm.

Hybrid systems continued to gain momentum as an area of interest. Sermpinis, Theofilatos, Karathanasopoulos, Georgopoulos, and Dunis (2013) develop a hybrid approach pairing neural network with particle swarm optimization to predict foreign exchange rates. Evans, Pappas, and Xhafa (2013) create a hybrid system for genetic algorithms and artificial neural networks applied to intra-day market prediction. Manahov and Hudson (2013) combine agent based systems with genetic programming to evaluate the price of stocks represented by the Dow Jones Industrial Average, General Electric, and IBM. Nhu, Nitsuwat, and Sodanil (2013) combine the Firefly Algorithm and Adaptive Neuro-Fuzzy Inference System (ANFIS) and validate the approach compared with ANFIS trained by the Hybrid Algorithm, Back Propagation and Particle Swarm Optimization. Andriosopoulos, Doumpos, Papapostolou, and Pouliasis (2013) use a genetic algorithm paired with differential evolution algorithm for portfolio optimization and for addressing the problem of index-tracking in shipping stock and freight markets. D. Wang, Liu, and Wang (2013) predict the price trends of stock futures by proposing a new DT-

SVM (Decision Tree and Support Vector Machine) based on hybrid methods which overcome the problems encountered with alternative methods such as fuzzy logic, or genetic algorithms. Chen (2013) integrates particle swarm optimization with an adaptive-network-based fuzzy inference system (ANFIS) model to predict business failure.

Other approaches that are worth mentioning include machine learning, optimization, case-based reasoning, and evolutionary approaches. Benhayoun, Chairri, El Gonnouni, and Lyhyaoui (2013) employ a Support Vector Machine Model in order to predict a company's creditworthiness by using historical data. Liang and Qu (2013) use a Multi-objective Dynamic Multi-Swarm Particle Swarm Optimizer in order to overcome the difficulties involved in classical methods previously applied to portfolio optimization problems. Chuang (2013) employs case-based reasoning to predict business failures. Xiao, Che, Wang, and Yang (2013) analyze stock price movements by studying the technical pattern of stock prices and provide a strategy for case-based reasoning approaches. Canelas, Neves, and Horta (2013) combine a symbolic Aggregate approximation (SAX) technique (for identifying the relevant patterns) with an optimization kernel based on genetic algorithms (GA) for generating investment rules in order to define less risky trading strategies.

Artificial Intelligence and Financial Investing (2014)

Hybrid approaches increased in popularity with many researchers combining AI techniques. For example, Adhikari and Agrawal (2014) combine random walk with artificial neural networks to create a hybrid system that outperforms its respective parts when applied to forecasting financial data. Bagheri, Peyhani, and Akbari (2014) predict market trends using a hybrid system with swarm intelligence and a fuzzy inference system. Semaan, Harb, and Kassem (2014) demonstrate that neural network based approaches can outperform standard statistical analysis when predicting

exchange rates. Li (2014) applies a hybrid neural network and bee colony algorithm for gold price prediction. Sanz, Bernardo, Herrera, Bustince Sola, and Hagrass (2014) demonstrate a compact evolutionary interval-valued fuzzy rule-based classification system, which is able to predict the real world financial data more accurately. Oreski and Oreski (2014) create a new novel classifier based on Hybrid Genetic algorithm and artificial neural network which is able to find the most relevant data and spend less time in the search space. Costea (2014) combines neural networks with genetic algorithms and fuzzy logic to evaluate the performance of non-banking financial institutions. Pulido, Melin, and Castillo (2014) create a hybrid system by integrating neural networks with particle swarm optimization and fuzzy based system to predict the Mexican stock exchange. Kristjanpoller, Fadic, and Minutolo (2014) implement a hybrid neural network model to predict financial market volatility. Reid, Malan, and Engelbrecht (2014) focus on solving realistic portfolio problems by using the Particle Swarm Optimization (PSO) and the Ant Colony Optimization (ACO) algorithms in order to overcome the problem of the uncovered interest rate parity condition. F. Wang, Yu, and Cheung (2014) propose a new performance based reward strategy that combines the moving average and the trading range breakout in a particle swarm optimization scenario to predicting the stock price trends accurately.

Other approaches worth mentioning: Bertella, Pires, Feng, and Stanley (2014) use agent based techniques to support decision making in stock market evaluation. K.-Y. Shen and Tzeng (2014) use a neuro-fuzzy approach to financial performance evaluation evaluated on commercial banks in Taiwan. Aouni, Colapinto, and La Torre (2014) show that goal programming can be applied to various applications of portfolio selection problem and helps the financial decision maker improve their decision making process. Zheng, Zhou, Chen, and Ekedebe (2014) propose a new automated evaluation system, which utilizes machine learning to automatically predict risk based on the data in

the SEC EDGAR database. Finally, Yu, Miche, Séverin, and Lendasse (2014) focus on utilizing the Leave-One-Out-Incremental Extreme Learning Machine (LOO-IELM) in order to study the bankruptcy prediction problem.

Artificial Intelligence and Financial Investing (2015)

This article concludes with the first 2 quarters of the 2015 calendar year. We see hybrid systems continuing to garner interest in the academic community. Patel, Shah, Thakkar, and Kotecha (2015) use a hybrid approach consisting of support vector regression, random forest, and neural networks for stock market index prediction. Rather, Agarwal, and Sastry (2015) propose combining neural networks with linear models for stock market data prediction. Musto, Semeraro, Lops, DeGemmis, and Lekkas (2015) propose a new framework for personalized investment portfolios, which is based on a combining case based reasoning with diversification techniques. Silva, Vasconcelos, Barros, and Franca (2015) integrate case-based reasoning with neural networks for credit risk analysis. Iturriaga and Sanz (2015) propose a new hybrid model implemented with a multilayer perceptron and self-organizing map in order to identify new metrics of financial risks in US commercial banks. Finally, Two other approaches include examples where Chen and Chen (2015) propose a fuzzy system for making stock market predictions and Yang, Chen, and Huang (2015) advance agent based systems by illustrating a framework for developing agents to stock market trading which was shown to outperform current agent based approaches such as random traders.

FUTURE RESEARCH DIRECTIONS

Artificial neural networks (ANN) remain the most popular form of AI technique in finance research (Bahrammirzaee, 2010). ANN approaches have been shown to outperform other techniques such as

genetic algorithms and multivariate discriminant analysis by more than 5% and 18% respectively (Rafiei et al., 2011). Research has moved away from a purely ANN approach to hybrid approaches, such as ANN and support vector machines, ANN and evolutionary computing, as well as ANN and fuzzy approaches. Future research will benefit from refining the hybrid AI approaches as well as incorporating additional AI techniques into hybrid systems when applied to finance. As big data and data science emerge, one would expect to see more literature encompassing related techniques. Future directions would benefit from increasing the variety and mixture of hybrid techniques while exploiting data science and big data concepts such as parallel processing (map reduce) or even real-time stream mining.

CONCLUSION

This article presents an overview of artificial intelligence applied to financial investing. First, the background of AI techniques and finance are discussed. Following the background, the focus of the article is identifying the direction of AI in finance from 2009 to 2013 and subsequently 2013 to the first half of 2015. A trend has been shown that single AI techniques dominated early research and progresses toward hybrid approaches. Neural networks remained one of the most popular methods throughout the literature and, as hybrid systems advanced, neural networks were one of the most common techniques included in hybrid systems.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: The ability of a computer to perform activities which are normally considered to require human intelligence.

Asset Valuation: The process of determining the worth of something.

Case-Based Reasoning: The process of solving new problems based on successful past solutions to similar problems.

Decision Tree: A tree like structure for modeling decisions and classifying data.

Evolutionary Computing: Branch of artificial intelligence which mimics biological evolution and often applied to optimization problems.

Expert System: A program that uses knowledge and inferences to solve problems in a way that experts might.

Fuzzy Systems: Systems which deal in approximations as opposed to exact representations (i.e. true/ false).

Genetic Algorithm: An algorithm that mimics the genetic concepts of natural selection, combination, selection, and inheritance.

Hybrid System: A system which employs a combination of techniques and methods.

Investing: The act of committing money to an endeavor with the expectation of obtaining profit.

Machine Learning: A method of automatically learning patterns from data in order to make future predictions.

Neural Networks: Programs that simulate a network of communicating nerve cells to achieve a machine learning objective.

Risk Management: The process of managing the uncertainty in investment decision-making.

Support Vector Machines (SVM): Supervised learning model to analyze data and predict which possible classes form the output.

Swarm Intelligence: Intelligence based on many individuals and decentralized control and self-organization.

Distributed Parameter Systems Control and Its Applications to Financial Engineering

INTRODUCTION

In several problems of financial engineering, such as options and commodities trading, forecasting of options' values, estimation of financial distress and credit risk assessment, validation of option pricing models, etc. one comes against Partial Differential Equations (PDEs). Moreover, in problems of control of financial systems where the aim is to stabilize financial processes which are described by PDE models, one has to harness again the complex PDE dynamics through the application of an external input. In the recent years differential flatness theory has emerged as an approach to the control and stabilization of systems described by PDE dynamics (Rudolph, 2003), (Rigatos, 2015). This research work focuses on differential flatness theory for the control and stabilization of single asset and multi-asset option price dynamics, described by PDE models. It is shown how the differential flatness approach achieves, stabilization of distributed parameter financial systems (that is systems modelled by PDEs) and how it enables convergence to specific financial performance indexes (Rigatos, 2014a; Rigatos, 2014b; Rigatos, 2014c; Rigatos, 2015a; Rigatos, 2015b; Rigatos, 2015c).

The Black-Scholes PDE is the principal financial model used in this study. It is demonstrated how with the use of semi-discretization and a finite differences scheme the single-asset (equivalently multi-asset) Black-Scholes PDE is transformed into a state-space model consisting of ordinary

nonlinear differential equations. For this set of differential equations it is proven that differential flatness properties hold (Rigatos, 2011; Rigatos, 2013; Rigatos, 2015). This permits to arrive at a solution for the associated control problem and to ascertain stabilization of the options' dynamics. By proving that it is feasible to control the single-asset (equivalently multi-asset) Black-Scholes PDE it is also concluded that through a selected trading policy, the price of options can be made to converge and stabilize at specific reference values.

The computational part of the considered feedback control method is as follows: For the local subsystems, into which the single-asset (equivalently multi-asset) Black-Scholes PDE is decomposed, it becomes possible to apply boundary-based feedback control. The controller design proceeds by showing that the state-space model of the single-asset (equivalently multi-asset) Black-Scholes PDE stands for a differentially flat system. Next, for each subsystem which is related to a nonlinear ODE, a virtual control input is computed, that can invert the subsystem's dynamics and can eliminate the subsystem's tracking error. From the last row of the state-space description, the control input (boundary condition) that is actually applied to the single-asset (equivalently multi-asset) Black-Scholes PDE system is found. This control input contains recursively all virtual control inputs which were computed for the individual ODE subsystems associated with the previous rows of the state-space equation. Thus, by tracing the rows of the state-space model

DOI: 10.4018/978-1-5225-2255-3.ch002

backwards, at each iteration of the control algorithm, one can finally obtain the control input that should be applied to the single-asset (equivalently multi-asset) Black-Scholes PDE system so as to assure that all its state variables will converge to the desirable setpoints.

The structure of the chapter is as follows: in Section “*The problem of boundary control of the single-asset Black-Scholes PDE*”, an overview about the single-asset Black-Scholes PDE is given and the associated boundary control problem is formulated. In Section “*Option pricing modelling with the use of the single-asset Black-Scholes PDE*” the concept of option pricing for the single-asset Black-Scholes PDE is explained. In Section “*Transformation of the single-asset Black-Scholes PDE into nonlinear ODEs*” it is explained how the single-asset Black-Scholes PDE dynamics can be transformed to an equivalent state-space form. In Section “*Computation of boundary control for the single-asset Black-Scholes PDE*” a boundary feedback control law is computed for the single-asset Black-Scholes PDE. In Section “*Closed loop dynamics of the single-asset Black-Scholes PDE*” the dynamics of the closed control loop of the single-asset Black-Scholes PDE is analysed. In Section “*The problem of boundary control of the multi-asset Black-Scholes PDE*” the multi-asset Black-Scholes PDE is introduced and the associated boundary control problem is formulated. In Section “*Boundary control of the multi-asset Black-Scholes PDE*” it is explained how the multi-asset Black-Scholes PDE can be transformed into an equivalent state-space description. In Section “*Flatness-based control of the multi-asset Black-Scholes PDE*” it is analysed how a boundary feedback control input can be computed for the multi-asset Black-Scholes PDE. In Section “*Simulation tests*” the satisfactory performance of the control loop is confirmed through simulation experiments for both the single-asset and the multi-asset Black-Scholes PDE. Finally, in Section “*Conclusions*” concluding remarks are stated.

BACKGROUND

One can note two modelling approaches for describing option price dynamics. The first one makes use of stochastic differential equations (SDEs). The underlying asset evolves according to a stochastic process that is driven by a random input. Using this representation, stochastic control methods for option price SDE diffusion models have been developed (Bensoussan, 2000), (Pascucci, 2011). Moreover, according to Kolmogorov’s theory, diffusion stochastic processes can be equivalently represented by partial differential equations (PDEs). These provide as solution the spatiotemporal distribution of the options’ value. The Black-Scholes PDE is such a relation (Platen & Heath, 2008; Sircar & Papanicolaou, 1998). Consequently, methods for PDE boundary control can be used for modifying option price dynamics. This topic will be elaborated in this article.

THE PROBLEM OF BOUNDARY CONTROL OF THE SINGLE-ASSET BLACK-SCHOLES PDE

Control and stabilization of financial systems is a difficult problem since the associated models have spatiotemporal dynamics and are either described by partial differential equations or by stochastic differential equations (Platen & Heath, 2006; Pascucci, 2011). On the one side control approaches for financial systems have been developed with the use of stochastic differential equations (Oksendal & Sulem, 2006; Stojanovic, 2007; Yin et al., 2010). On the other side, control of financial dynamics through the use of the associated partial differential equations description remains an open problem for which efficient solutions have to be provided (Rudolph, 2003; Smyshlyaev & Krstic, 2010). To this end, in this research work a new control method is developed for the diffusion-type of the Black-Scholes PDE which describes the dynamics of options in financial markets. It is

shown that boundary control, that is control based on the boundary conditions of the PDE, can be exerted on the Black-Scholes PDE thus modifying its dynamics and leading the options' prices to converge to specific reference values. Controlling the dynamics of financial systems with the application of exogenous inputs and feedback has been attempted in several research works (Miller & Weller, 1995; Barmish, 2011; Fliess & Join, 2012; Fliess & Join, 2010). Control of financial systems is important for minimizing default risks, maximizing profits or stabilizing the dynamics of stock market indexes (Fedorov & Mikhailov, 2001; Forsyth & Labahn, 2007; Bernhard, 2006; Windcliff et al., 2004). The present chapter treats the problem of boundary control of the nonlinear Black-Scholes PDE, which means that the boundary conditions are used as control inputs to modify this PDE dynamics. Boundary control or lumped-input control of nonlinear distributed parameter systems are problems of elevated difficulty and many remarkable results on this topic exist (Woitteneck & Mounier, 2010; Mounier et al., 2010; Fliess & Mounier, 2002; Boussaada et al., 2013). If the PDE system is decomposed into an equivalent set of ordinary nonlinear differential equations, then controlling such a set of dynamical subsystems by the boundary conditions implies underactuation.

The control approach followed in this chapter is as follows: First, by implementing a procedure as in the numerical solution of the Black-Scholes PDE a set of equivalent nonlinear ordinary differential equations is obtained (Pinsky, 1991; Gerdtz et al., 2008; Guo & Billings 2007; Kroner, 2011; Winkler & Lohmann, 2010; Dragonescu & Soane, 2013). Next it is shown that the system of the nonlinear ODEs is a differentially flat one. This means that all its state variables and the control inputs can be written as differential functions of one single algebraic variable which is the flat output (Sira-Ramirez & Agrawal, 2004; Lévine, 2009; Bououden et al., 2011; Fliess & Mounier, 1999; Lévine, 2011). Moreover, by examining independently each nonlinear ODE it is shown

that this stands again for a differentially flat system, for which a virtual control input can be computed as in the case of flatness-based control for the trivial system. The virtual control input is chosen such that the ODE subsystem dynamics is linearized and the tracking error is eliminated. The boundary condition that appears in the nonlinear ODE subsystem that comprises the last row of the state-space description, stands for the aggregate control input. The computation of the boundary control input uses recursively all virtual control inputs mentioned above, moving from the last ODE system to the first one. Thus, by tracing the rows of the state-space model backwards, at each iteration of the control algorithm, one can finally obtain the control input that should be applied to the Black-Scholes PDE system so as to assure that all its state vector elements will converge to the desirable setpoints. By analyzing the dynamics of the closed-loop system that results from the application of the aforementioned control method, asymptotic stability is confirmed.

OPTION PRICING MODELLING WITH THE USE OF THE SINGLE-ASSET BLACK-SCHOLES PDE

Definition of Options

A financial derivative is called a European option if it gives the right for pay-off according to a function $H : [0, \infty] \rightarrow R$ which has as principle variable the security index S_t , while there is also a predefined expiration date $T \in [0, \infty)$. If the payoff can take place before the expiration date then one has an American option. The value function of a European option is denoted as $V(t, S_t)$, where t varies in the interval $t \in [0, T]$, while the associated payoff function is defined as H and the maturity time is $T \in [0, \infty)$. The value function $V : [0, T] \times [0, \infty) \rightarrow R$ for a European option, can be differentiated with respect to time while it is also twice differentiable with respect to the security index S .

Option Price Modelling with The Use of Stochastic Differential Equations

The option price model assumes that the security price $S = \{S_t, t \in [0, T]\}$ with initial value equal to S_0 follows a geometric Brownian motion

$$dS_t = a_t S_t dt + \sigma_t S_t dW_t \quad (1)$$

where $a = \{a_t, t \in [0, T]\}$ is the appreciation rate which is a positive variable, and $\sigma = \{\sigma_t, t \in [0, T]\}$ is the volatility parameter. Variable W denoted a Wiener process, $W = \{W_t, t \in [0, T]\}$. There is also a second stochastic process in the model which is given by

$$dB_t = r_t B_t dt \quad (2)$$

where B_t corresponds to the domestic savings parameter $B = \{B_t, t \in [0, T]\}$ with initial value $B_0 = 1$. Variable r_t is the interest rate $r = \{r_t, t \in [0, T]\}$. The domestic savings account is also called locally riskless asset when there is no noise term in the SDE model given in Eq. (2).

The Black-Scholes PDE

A model that is equivalent to the SDE description of option price dynamics is provided by the Black-Scholes PDE (Platen & Heath, 2006; Pascucci, 2011). The Black-Scholes partial differential equation is given by

$$\frac{\partial V(t, S)}{\partial t} + r_t S \frac{\partial V(t, S)}{\partial S} + \frac{1}{2} \sigma_t^2 S^2 \frac{\partial^2 V(t, S)}{\partial S^2} - r_t V(t, S) = 0 \quad (3)$$

For $t \in (0, T)$ and $S \in (0, \infty)$ where r is the interest rate and σ_t is the volatility, while the associated terminal condition is

$$V(T, S) = H(S) \quad (4)$$

Equation 3 and Equation 4 form the Black-Scholes partial differential equation. The Black-Scholes PDE is a diffusion partial differential equation which describes the evolution of the option's price distribution $V(t, S)$, as a function of time t and of the underlying asset (security index) S .

TRANSFORMATION OF THE SINGLE-ASSET BLACK-SCHOLES PDE INTO NONLINEAR ODES

Next, the following nonlinear Black-Scholes PDE is considered:

$$\frac{\partial V(t, S)}{\partial t} + r_t S \frac{\partial V(t, S)}{\partial S} + \frac{1}{2} \sigma_t^2 S^2 \frac{\partial^2 V(t, S)}{\partial S^2} - r_t V(t, S) = 0 \quad (5)$$

It is assumed that the volatility σ_t has a nonlinear dependence on V_{ss} that is

$$\sigma_t = \sigma(V_{ss}) \quad (6)$$

where $V_{ss} = \frac{\partial^2 V(t, S)}{\partial S^2}$ and σ is a nonlinear function. A grid of N points is considered, that is $\{s_1, s_2, \dots, s_{N-1}, s_N\}$ which are placed at equal distances on the S axis. At the points of spatial discretization, it holds

$$\frac{\partial V(t, S_i)}{\partial t} = r_t V(t, S_i) - r_t S_i \frac{\partial V(t, S_i)}{\partial S} - \frac{1}{2} \sigma_t^2 S_i^2 \frac{\partial^2 V(t, S_i)}{\partial S^2} \quad (7)$$

where $i = 1, 2, \dots, N$. The following state vector is defined as shown in Box 1.

Box 1.

A

$$\tilde{V} = [V(t, s_1), V(t, s_2), V(t, s_3), \dots, V(t, s_{N-1}), V(t, s_N)] \quad \text{ur} \quad (8)$$

$$\tilde{V} = [V_1, V_2, V_3, \dots, V_{N-1}, V_N]$$

thus one has

$$\begin{aligned} \frac{\partial V_1}{\partial t} &= r_1 V_1 - r_1 S_1 \frac{V_2 - V_1}{\Delta S} - \frac{1}{2} \sigma_t^2(V_{ss}) S_1^2 \frac{V_2 - 2V_1 + V_0}{\Delta S^2} \\ \frac{\partial V_2}{\partial t} &= r_1 V_2 - r_1 S_2 \frac{V_3 - V_2}{\Delta S} - \frac{1}{2} \sigma_t^2(V_{ss}) S_2^2 \frac{V_3 - 2V_2 + V_1}{\Delta S^2} \\ \frac{\partial V_3}{\partial t} &= r_1 V_3 - r_1 S_3 \frac{V_4 - V_3}{\Delta S} - \frac{1}{2} \sigma_t^2(V_{ss}) S_3^2 \frac{V_4 - 2V_3 + V_2}{\Delta S^2} \\ &\dots \dots \dots \\ \frac{\partial V_{N-1}}{\partial t} &= r_1 V_{N-1} - r_1 S_{N-1} \frac{V_N - V_{N-1}}{\Delta S} - \frac{1}{2} \sigma_t^2(V_{ss}) S_{N-1}^2 \frac{V_N - 2V_{N-1} + V_{N-2}}{\Delta S^2} \\ &\dots \dots \dots \\ \frac{\partial V_{N-1}}{\partial t} &= r_1 V_N - r_1 S_N \frac{V_{N+1} - V_N}{\Delta S} - \frac{1}{2} \sigma_t^2(V_{ss}) S_N^2 \frac{V_{N+1} - 2V_N + V_{N-1}}{\Delta S^2} \end{aligned} \quad (9)$$

For the i-th ODE one has at sampling point S_i along the S axis one has

$$\begin{aligned} \frac{\partial V_i}{\partial t} &= r_i V_i - r_i S_i \frac{V_{i+1} - V_i}{\Delta S} - \frac{1}{2} \sigma_t^2(V_{ss}) S_i^2 \frac{V_{i+1}}{\Delta S^2} + \\ &\sigma_t^2(V_{ss}) S_i^2 \frac{V_i}{\Delta S^2} - \frac{1}{2} \sigma_t^2(V_{ss}) S_i^2 \frac{V_{i-1}}{\Delta S^2} \end{aligned} \quad (10)$$

Equation 32 is also written in the form

$$\begin{aligned} \frac{\partial V_i}{\partial t} &= -\frac{1}{2} \frac{\sigma_t^2(V_{ss})}{\Delta S^2} S_i^2 V_{i-1} + \frac{\sigma_t^2(V_{ss})}{\Delta S^2} S_i^2 V_i - \\ &[\frac{r_i S_i}{\Delta S} + \frac{1}{2} \frac{\sigma_t^2(V_{ss})}{\Delta S^2} S_i^2] V_{i+1} + [r_i + \frac{r_i S_i}{\Delta S}] V_i \end{aligned} \quad (11)$$

Next, by denoting $K_1 = -\sigma_t^2(V_{ss}) S_i^2$,

$$K_2 = -[2r_i S_i \Delta S + \sigma_t^2(V_{ss}) S_i^2]$$

and $f(V_i) = [r_i + \frac{r_i S_i}{\Delta S}] V_i$ one obtains the following description for Equation 11

$$\begin{aligned} \frac{\partial V_i}{\partial t} &= \frac{K_1}{2\Delta S^2} V_{i-1} - \frac{K_1}{\Delta S^2} V_i + \\ &\frac{K_2}{\Delta S^2} V_{i+1} + f(V_i) \end{aligned} \quad (12)$$

For the i-th ODE where $i = 1, 2, \dots, N$, coefficients K_1 and K_2 are computed at the local grid point S_i . Next, the following state vector is defined for the PDE model:

$$\tilde{Y} = [y_{1,1}, y_{1,2}, \dots, y_{1,i}, \dots, y_{1,N-1}, y_{1,N}]$$

where $y_{1,1} = V_1$, $y_{1,2} = V_2 \dots y_{1,N-1} = V_{N-1}$ and $y_{1,N} = V_N$. It will be shown that the state-space description of the nonlinear PDE dynamics

Box 2.

$$\dot{y}_{1,N} = \frac{K_1}{\Delta S^2} y_{1,N} + f(y_{1,N}) + \frac{K_2}{2\Delta S^2} \phi_{N+1} + \frac{K_1}{2\Delta S^2} y_{1,N-1} \quad (13)$$

$$\dot{y}_{1,N-1} = \frac{K_1}{\Delta S^2} y_{1,N-1} + f(y_{1,N-1}) + \frac{K_2}{2\Delta S^2} y_N + \frac{K_1}{2\Delta S^2} y_{1,N-2} \quad (14)$$

$$\dot{y}_{1,N-2} = \frac{K_1}{\Delta S^2} y_{1,N-2} + f(y_{1,N-2}) + \frac{K_2}{2\Delta S^2} y_{N-1} + \frac{K_1}{2\Delta S^2} y_{1,N-3} \quad (15)$$

$$\dot{y}_{1,i} = \frac{K_1}{\Delta S^2} y_{1,i} + f(y_{1,i}) + \frac{K_2}{2\Delta S^2} y_{1,i+1} + \frac{K_1}{2\Delta S^2} y_{1,i-1} \quad (16)$$

$$\dot{y}_{1,3} = \frac{K_1}{\Delta S^2} y_{1,3} + f(y_{1,3}) + \frac{K_2}{2\Delta S^2} y_{1,4} + \frac{K_1}{2\Delta S^2} y_{1,2} \quad (17)$$

$$\dot{y}_{1,2} = \frac{K_1}{\Delta S^2} y_{1,2} + f(y_{1,2}) + \frac{K_2}{2\Delta S^2} y_{1,3} + \frac{K_1}{2\Delta S^2} y_{1,1} \quad (18)$$

$$\dot{y}_{1,1} = \frac{K_1}{\Delta S^2} y_{1,1} + f(y_{1,1}) + \frac{K_2}{2\Delta S^2} y_{1,2} + \frac{K_1}{2\Delta S^2} \phi_0 \quad (19)$$

It can be proven that the state-space model of the Black-Scholes PDE is a differentially flat one, considering as flat output $y_{1,1} = V_1$. This means that all state variables and the control inputs of the model can be expressed as differential functions of this flat output. Moreover, by examining the i -th row of the state-space description as an independent subsystem with output x_i and virtual control input x_{i+1} it can be shown that this subsystem is also differentially flat with local flat output x_i .

COMPUTATION OF BOUNDARY CONTROL FOR THE SINGLE-ASSET BLACK-SCHOLES PDE

To implement boundary feedback control, the nonlinear diffusion-PDE model is rewritten as shown in Box 2.

The boundary condition ϕ_{N+1} is assumed to be known and remains steady. The boundary

condition ϕ_0 stands for the control input (for example, it can be dependent on the interest rate). The feedback control law is designed as follows:

$$a_1 = y_{1,N-1}^* = \frac{1}{(K_1 / 2\Delta S^2)} [\dot{y}_{1,N} - k_{p,1}(y_{1,N} - y_{1,N}^d)] + \frac{K_1}{\Delta S^2} y_{1,N} - f(y_{1,N}) - \frac{K_2}{2\Delta S^2} \phi_{N+1} \quad (20)$$

$$\begin{aligned} a_2 = y_{1,N-2}^* = & \frac{1}{(K_1 / 2\Delta S^2)} [\dot{y}_{1,N-1} - k_{p,2}(y_{1,N-1} - y_{1,N-1}^d)] \\ & + \frac{K_1}{\Delta S^2} y_{1,N-1} - f(y_{1,N-1}) - \frac{K_2}{2\Delta S^2} y_N \\ \Rightarrow a_2 = & \frac{1}{(K_1 / 2\Delta S^2)} [a_1 - k_{p,2}(y_{1,N-1} - a_1)] + \\ & \frac{K_1}{\Delta S^2} y_{1,N-1} - f(y_{1,N-1}) - \frac{K_2}{2\Delta S^2} y_N \end{aligned} \quad (21)$$

$$\begin{aligned}
a_3 &= y_{1,N-3}^* = \\
&\frac{1}{(K_1 / 2\Delta S^2)} [\dot{y}_{1,N-2} - k_{p,3}(y_{1,N-2} - y_{1,N-2}^d)] + \\
&\frac{K_1}{\Delta S^2} y_{1,N-2} - f(y_{1,N-2}) - \frac{K_2}{2\Delta S^2} y_{N-1} \\
\Rightarrow a_3 &= \frac{1}{(K_1 / 2\Delta S^2)} [\dot{a}_2 - k_{p,3}(y_{1,N-2} - a_2)] + \\
&\frac{K_1}{\Delta S^2} y_{1,N-2} - f(y_{1,N-2}) - \frac{K_2}{2\Delta S^2} y_N
\end{aligned} \tag{22}$$

and continuing in a similar manner

$$\begin{aligned}
a_i &= y_{1,N-i}^* = \\
&\frac{1}{(K_1 / 2\Delta S^2)} [\dot{y}_{1,N-i+1} - k_{p,i}(y_{1,N-i+1} - y_{1,N-i+1}^d)] + \\
&\frac{K_1}{\Delta S^2} y_{1,N-i+1} - f(y_{1,N-i+1}) - \frac{K_2}{2\Delta S^2} y_{N-i+2} \\
\Rightarrow a_i &= \\
&\frac{1}{(K_1 / 2\Delta S^2)} [\dot{a}_{i-1} - k_{p,i}(y_{1,N-i+1} - a_{i-1})] + \\
&\frac{K_1}{\Delta S^2} y_{1,N-i+1} - f(y_{1,N-i+1}) - \frac{K_2}{2\Delta S^2} y_{N-i+2}
\end{aligned} \tag{23}$$

Following this procedure one arrives to compute the control inputs which are associated with the last two rows of the state-space model

$$\begin{aligned}
a_{N-2} &= y_{1,2}^* = \\
&\frac{1}{(K_1 / 2\Delta S^2)} [\dot{y}_{1,3} - k_{p,N-2}(y_{1,3} - y_{1,3}^d)] \\
&+ \frac{K_1}{\Delta S^2} y_{1,3} - f(y_{1,3}) - \frac{K_2}{2\Delta S^2} y_{1,4} \\
\Rightarrow a_{N-2} &= \\
&\frac{1}{(K_1 / 2\Delta S^2)} [\dot{a}_{N-3} - k_{p,N-2}(y_{1,3} - a_{N-3})] \\
&+ \frac{K_1}{\Delta S^2} y_{1,3} - f(y_{1,3}) - \frac{K_2}{2\Delta S^2} y_{1,4}
\end{aligned} \tag{24}$$

$$\begin{aligned}
a_{N-1} &= y_{1,1}^* = \\
&\frac{1}{(K_1 / 2\Delta S^2)} [\dot{y}_{1,2} - k_{p,N-1}(y_{1,2} - y_{1,2}^d)] \\
&+ \frac{K_1}{\Delta S^2} y_{1,2} - f(y_{1,2}) - \frac{K_2}{2\Delta S^2} y_{1,3} \\
\Rightarrow a_{N-1} &= \\
&\frac{1}{(K_1 / 2\Delta S^2)} [\dot{a}_{N-2} - k_{p,N-1}(y_{1,2} - a_{N-2})] \\
&+ \frac{K_1}{\Delta S^2} y_{1,2} - f(y_{1,2}) - \frac{K_2}{2\Delta S^2} y_{1,3}
\end{aligned} \tag{25}$$

and finally

$$\begin{aligned}
a_N &= \phi_0 = \frac{1}{(K_1 / 2\Delta S^2)} [\dot{y}_{1,1} - k_{p,N}(y_{1,1} - y_{1,1}^d)] \\
&+ \frac{K_1}{\Delta S^2} y_{1,1} - f(y_{1,1}) - \frac{K_2}{2\Delta S^2} y_{1,2} \\
\Rightarrow a_N &= \frac{1}{(K_1 / 2\Delta S^2)} [\dot{a}_{N-1} - k_{p,N}(y_{1,1} - a_{N-1})] \\
&+ \frac{K_1}{\Delta S^2} y_{1,1} - f(y_{1,1}) - \frac{K_2}{2\Delta S^2} y_{1,2}
\end{aligned} \tag{26}$$

Consequently, the computation of the aggregate control input $a_N = \phi_0$ which is exerted on the PDE model is performed by moving backwards, and by substituting recursively into ϕ_0 the virtual control inputs $a_{N-1}, a_{N-2}, \dots, a_i, \dots, a_2, a_1$. It is noted that implementation of flatness-based control in cascaded loops has been studied in the case of lumped parameter systems, as for example in electric machines (Dannehl & Fuchs, 2006; Rigatos & Siano, 2002; Rigatos & Siano, 2012). The approach followed in this paper extends this concept to a problem of elevated difficulty, and with a state-space description of higher dimensionality, that is control of distributed parameter systems and in particular control of the Black-Scholes PDE.

CLOSED LOOP DYNAMICS OF THE SINGLE-ASSET BLACK-SCHOLES PDE

By substituting Equation 26 into Equation 19 of the state-space model of the PDE dynamics, and using the definition $y_{1,1} - y_{1,1}^d = z_1$ one has

$$\begin{aligned} \dot{y}_{1,1} &= \dot{y}_{1,1}^d - k_{p,1}(y_{1,1} - y_{1,1}^d) \Rightarrow \\ (\dot{y}_{1,1} - \dot{y}_{1,1}^d) + k_{p,1}(y_{1,1} - y_{1,1}^d) &= 0 \Rightarrow \\ z_1 + k_{p,1}z_1 &= 0 \end{aligned} \quad (27)$$

Equivalently, by substituting Equation 25 into Equation 18, and using the definition $y_{1,2} - a_1 = z_2$ one has

$$\begin{aligned} \dot{y}_{1,2} &= \dot{a}_1 - k_{p,2}(y_{1,2} - a_1) \Rightarrow \\ (\dot{y}_{1,2} - \dot{a}_1) + k_{p,2}(y_{1,2} - a_1) &= 0 \Rightarrow \\ z_2 + k_{p,2}z_2 &= 0 \end{aligned} \quad (28)$$

Similarly, continuing with the rest of the equations of the state-space model and by substituting Equation 24 into Equation 17, while also using the definition $y_{1,3} - a_2 = z_3$ one has

$$\begin{aligned} \dot{y}_{1,3} &= \dot{a}_2 - k_{p,3}(y_{1,3} - a_2) \Rightarrow \\ (\dot{y}_{1,3} - \dot{a}_2) + k_{p,3}(y_{1,3} - a_2) &= 0 \Rightarrow \\ z_3 + k_{p,3}z_3 &= 0 \end{aligned} \quad (29)$$

Moving backwards, and by substituting Equation 23 into Equation 16 of the state-space model of the PDE dynamics, and using the definition $y_{1,i} - a_{i-1} = z_i$ one has

$$\begin{aligned} \dot{y}_{1,i} &= \dot{a}_{i-1} - k_{p,i}(y_{1,i} - a_{i-1}) \Rightarrow \\ (\dot{y}_{1,i} - \dot{a}_{i-1}) + k_{p,i}(y_{1,i} - a_{i-1}) &= 0 \Rightarrow \\ z_i + k_{p,i}z_i &= 0 \end{aligned} \quad (30)$$

By substituting Equation 21 into Equation 14 of the state-space model of the PDE dynamics, and using the definition $y_{1,N-1} - a_{N-2} = z_{N-1}$ one has

$$\begin{aligned} \dot{y}_{1,N-1} &= \dot{a}_{N-2} - k_{p,N-1}(y_{1,N-1} - a_{N-2}) \Rightarrow \\ (\dot{y}_{1,N-1} - \dot{a}_{N-2}) + k_{p,N-1}(y_{1,N-1} - a_{N-2}) &= 0 \Rightarrow \\ z_{N-1} + k_{p,N-1}z_{N-1} &= 0 \end{aligned} \quad (31)$$

Finally, by substituting Equation 20 into Equation 13, and using the definition $y_{1,N} - a_{N-1} = z_N$ one obtains

$$\begin{aligned} \dot{y}_{1,N} &= \dot{a}_{N-1} - k_{p,N}(y_{1,N} - a_{N-1}) \Rightarrow \\ (\dot{y}_{1,N} - \dot{a}_{N-1}) + k_{p,N}(y_{1,N} - a_{N-1}) &= 0 \Rightarrow \\ z_N + k_{p,N}z_N &= 0 \end{aligned} \quad (32)$$

Thus, the dynamics of the closed-loop system becomes

$$\begin{aligned} z_1 + k_{p,1}z_1 &= 0 \\ z_2 + k_{p,2}z_2 &= 0 \\ z_3 + k_{p,3}z_3 &= 0 \\ \dots\dots\dots \\ z_i + k_{p,i}z_i &= 0 \\ \dots\dots\dots \\ z_{N-1} + k_{p,N-1}z_{N-1} &= 0 \\ z_N + k_{p,N}z_N &= 0 \end{aligned} \quad (33)$$

The dynamics of the closed-loop system can be also written in matrix form

$$\dot{\tilde{Z}} + K_p \tilde{Z} = 0 \quad (34)$$

where

$$\tilde{Z} = [z_1, z_2, z_3, \dots, z_i, \dots, z_{N-1}, z_N],$$

and

$$K_p = \text{diag}[k_{p_1}, k_{p_2}, k_{p_3}, \dots, k_{p_i}, \dots, k_{p_{N-1}}, k_{p_N}].$$

After suitable selection of the coefficients k_{p_i} , $i = 1, 2, \dots, N$ such that the monomials $p(s) = s + k_{p_i}$ to have a negative root, it can be assured that $\lim_{t \rightarrow \infty} z_i(t) = 0$ and that the closed-loop system is asymptotically stable. Moreover, to prove asymptotic stability for the closed-loop system, the following Lyapunov function can be used

$$V_L = \sum_{i=1}^N \frac{1}{2} z_i^2 \quad (35)$$

The derivative of this Lyapunov function with respect to time is given by

$$\begin{aligned} \dot{V}_L &= \sum_{i=1}^N z_i \dot{z}_i \Rightarrow \dot{V}_L = \sum_{i=1}^N z_i (-k_{p_i} z_i) \Rightarrow \\ \dot{V}_L &= -\sum_{i=1}^N k_{p_i} z_i^2 < 0 \end{aligned} \quad (36)$$

Thus, it is proven again that the closed-loop system is globally asymptotically stable.

THE PROBLEM OF BOUNDARY CONTROL OF THE MULTI-ASSET BLACK-SCHOLES PDE

A multi-asset option price model is considered next. In such a case, the dynamics of the options' value is described by the multi-asset Black-Scholes PDE (Wade et al., 2007; Moon & Kim, 2013; Lotstedt et al., 2007; Moon et al., 2006; Martins-Vaquero et al., 2014). The chapter treats also the problem of feedback control and stabilization of the aforementioned PDE. As already noted, methods for feedback stabilization of systems with nonlinear PDE dynamics have been a flourishing research subject in the last years (Balogh & Kristic, 2002; Bensoussan et al., 2006; Basseville & Nikiforov, 1993; Boussaada et al., 2013; Smyshlyaev & Krstic, 2010; Boskovic et al., 2002; Liu, 2003). In particular, feedback control of diffusion-type (parabolic) PDEs has been a subject of extensive research and several remarkable results have been produced (Maidi & Corriou, 2014; Zwart et al., 2011; Woitteneck & Mounier, 2010; Mounier et al., 2010). As already pointed out, for the control of diffusion PDEs, boundary and distributed control methods have been developed (Fliess & Mounier, 2002; Rigatos, 2015a; Winkler & Lohmann, 2010). By showing the feasibility of control of the multi-asset Black-Scholes PDE it is also proven that through a selected trading policy, the price of options can be made to converge and stabilize at specific reference values. By applying semi-discretization and the finite differences method, the multi-asset Black-Scholes PDE model is written in a state-space form (Olivier & Sedoglavic, 2001; Kroner, 2011). This state-space description stands for a differentially flat system which means that all its state variables and control inputs can be written as differential functions of the flat output vector (Bououden et al., 2011; Lévine, 2009; Lévine, 2011). One can note several results on the use of differential flatness theory in the

control of PDEs (Rudolph, 2003; Rigatos, 2013; Rigatos, 2015b). The first stage in the proposed control approach for the multi-asset Black-Scholes PDE is to decompose the state-space description of the PDE into an equivalent set of nonlinear ODEs (Guo & Billings, 2007; Pinsky, 1991; Utz et al., 2011; Laroche, 2000). Next by examining independently each nonlinear ODE it is shown that this stands again for a differentially flat system, for which a virtual control input can be computed as in the case of flatness-based control for the trivial system. The virtual control input is chosen such that the ODE subsystem dynamics is linearized and the tracking error is eliminated. The boundary condition that appears in the nonlinear ODE subsystem that comprises the last row of the state-space description, stands again for the aggregate control input.

The computation of the boundary control input uses recursively all virtual control inputs mentioned above, moving from the last ODE system to the first one. This stands for implementation of flatness-based control in successive (cascading) loops. Thus, by tracing the rows of the state-space model backwards, at each iteration of the control algorithm, one can finally obtain the control input that should be applied to the multi-asset Black-Scholes PDE system so as to assure that all its state vector elements will converge to the desirable setpoints. The stability of the control loop is proven in two manners. First, convergence to zero is proven for the tracking error of all subsystems into which the PDE's state-space model is decomposed. Next, with the use of Lyapunov analysis it is reconfirmed that this control scheme is asymptotically stable.

BOUNDARY CONTROL OF THE MULTI-ASSET BLACK-SCHOLES PDE

Next, the multi-asset Black-Scholes PDE is introduced (Martins-Vaquero et al., 2014; Wade et al., 2007):

$$\frac{\partial V}{\partial t} = \sum_{i=1}^N \sum_{j=1}^N \rho \sigma_i \sigma_j S_i S_j \frac{\partial^2 V}{\partial S_i \partial S_j} + \sum_{i=1}^N r S_i \frac{\partial V}{\partial S_i} - rV \quad (35)$$

Moreover, without loss of generality the two-asset Black-Scholes PDE is considered

$$\frac{\partial V}{\partial t} = \frac{1}{2} \sigma_1^2 S_1^2 \frac{\partial^2 V}{\partial S_1^2} + \frac{1}{2} \sigma_2^2 S_2^2 \frac{\partial^2 V}{\partial S_2^2} + \rho \sigma_1 \sigma_2 S_1 S_2 \frac{\partial^2 V}{\partial S_1 \partial S_2} + r S_1 \frac{\partial V}{\partial S_1} + r S_2 \frac{\partial V}{\partial S_2} - rV \quad (36)$$

Semi-discretization and the finite differences method is applied. To this end the partial derivatives appearing in Equation 36 are computed as follows:

$$\frac{\partial V}{\partial S_1} = \frac{V(S_{1,i+1}, S_{2,j}) - V(S_{1,i}, S_{2,j})}{\Delta S_1} \quad (37)$$

$$\frac{\partial^2 V}{\partial S_1^2} = \frac{V(S_{1,i+1}, S_{2,j}) - 2V(S_{1,i}, S_{2,j}) + V(S_{1,i-1}, S_{2,j})}{\Delta S_1^2} \quad (38)$$

$$\frac{\partial V}{\partial S_2} = \frac{V(S_{1,i}, S_{2,j+1}) - V(S_{1,i}, S_{2,j})}{\Delta S_2} \quad (39)$$

$$\frac{\partial^2 V}{\partial S_2^2} = \frac{V(S_{1,i}, S_{2,j+1}) - 2V(S_{1,i}, S_{2,j}) + V(S_{1,i}, S_{2,j-1})}{\Delta S_2^2} \quad (40)$$

Box 3.

A

$$\frac{\partial^2 V}{\partial S_1 \partial S_2} = \frac{V(S_{1,i+1}, S_{2,j+1}) - V(S_{1,j+1}, S_{2,j}) - V(S_{1,i}, S_{2,j+1}) + V(S_{1,i}, S_{2,j})}{\Delta S_1 \Delta S_2} \quad (41)$$

Using the previous semi-discretization, for grid point (i, j) it holds

$$\begin{aligned} \frac{\partial V(S_{1,i}, S_{2,j})}{\partial t} &= \frac{1}{2} \sigma_1^2 S_{1,i}^2 \left[\frac{V(S_{1,i+1}, S_{2,j}) - 2V(S_{1,i}, S_{2,j}) + V(S_{1,i-1}, S_{2,j})}{\Delta S_1^2} \right] + \\ &\frac{1}{2} \sigma_2^2 S_{2,j}^2 \left[\frac{V(S_{1,i}, S_{2,j+1}) - 2V(S_{1,i}, S_{2,j}) + V(S_{1,i}, S_{2,j-1})}{\Delta S_2^2} \right] + \\ &\rho \sigma_1 \sigma_2 S_{1,i} S_{2,j} \left[\frac{V(S_{1,i+1}, S_{2,j+1}) - V(S_{1,i+1}, S_{2,j}) - V(S_{1,i}, S_{2,j+1}) + V(S_{1,i}, S_{2,j})}{\Delta S_1 \Delta S_2} \right] + \\ &r S_{1,i} \left[\frac{V(S_{1,i+1}, S_{2,j}) - V(S_{1,i}, S_{2,j})}{\Delta S_1} \right] + r S_{2,j} \left[\frac{V(S_{1,i}, S_{2,j+1}) - V(S_{1,i}, S_{2,j})}{\Delta S_2} \right] - r V(S_{1,i}, S_{2,j}) \end{aligned} \quad (42)$$

and in Equation 41 (shown in Box 3).

The boundary conditions of the PDE are taken to be $V_{i,0} \neq 0$ only if $i = 1$, $V_{0,j} \neq 0$ only if $j = 1$ and $V(i, j) = ct$ (constant) if $i > N$ or $j > N$.

Considering that $i = 1, 2, \dots, N$ and $j = 1, 2, \dots, N$ the option's values at the grid points (i, j) are denoted as $V_{i,j}$. Using this notation, the semi-discretized model of the PDE takes the following form: At grid point $i = 1$ and $j = 1$

$$\begin{aligned} \frac{\partial V_{1,1}}{\partial t} &= \frac{1}{2} \sigma_1^2 S_{1,1}^2 \left[\frac{V_{2,1} - 2V_{1,1} + V_{0,1}}{\Delta S_1^2} \right] + \\ &+ \frac{1}{2} \sigma_2^2 S_{2,1}^2 \left[\frac{V_{1,2} - 2V_{1,1} + V_{1,0}}{\Delta S_2^2} \right] + \\ &\rho \sigma_1 \sigma_2 S_{1,1} S_{2,1} \left[\frac{V_{2,2} - V_{2,1} - V_{1,2} + V_{1,1}}{\Delta S_1 \Delta S_2} \right] + \\ &+ r S_{1,1} \left[\frac{V_{2,1} - V_{1,1}}{\Delta S_1} \right] + r S_{2,1} \left[\frac{V_{1,2} - V_{1,1}}{\Delta S_2} \right] - r V_{1,1} \end{aligned} \quad (43)$$

At grid point $i > 1$ and $j > 1$ it holds

$$\begin{aligned} \frac{\partial V_{i,j}}{\partial t} &= \frac{1}{2} \sigma_1^2 S_{1,i}^2 \left[\frac{V_{i+1,j} - 2V_{i,j} + V_{i-1,j}}{\Delta S_1^2} \right] + \\ &+ \frac{1}{2} \sigma_2^2 S_{2,j}^2 \left[\frac{V_{i,j+1} - 2V_{i,j} + V_{i,j-1}}{\Delta S_2^2} \right] + \\ &\rho \sigma_1 \sigma_2 S_{1,i} S_{2,j} \left[\frac{V_{i+1,j+1} - V_{i+1,j} - V_{i,j+1} + V_{i,j}}{\Delta S_1 \Delta S_2} \right] + \\ &+ r S_{1,i} \left[\frac{V_{i+1,j} - V_{i,j}}{\Delta S_1} \right] + r S_{2,j} \left[\frac{V_{i,j+1} - V_{i,j}}{\Delta S_2} \right] - r V_{i,j} \end{aligned} \quad (44)$$

Next, the following state vector variables are defined $x_{(i-1)N+j} = V_{i,j}$, $i = 1, 2, \dots, N$ and $j = 1, 2, \dots, N$. The system's state vector becomes

$$x = [x_1, x_2, \dots, x_{(i-1)N+(j-1)}, x_{(i-1)N+j}, \dots, x_{N^2}]^T$$

and comprises N^2 elements. Using this notation of state variables Equation 81 becomes

$$\begin{aligned}
 \dot{x}_1 = & \frac{1}{2} \sigma_1^2 S_{1,1}^2 \left[\frac{x_{N+1} - 2x_1}{\Delta S_1^2} \right] + \\
 & \frac{1}{2} \sigma_2^2 S_{2,1}^2 \left[\frac{x_2 - 2x_1}{\Delta S_1^2} \right] + \\
 & + \rho \sigma_1 \sigma_2 S_{1,1} S_{1,2} \left[\frac{x_{N+2} - x_2 - x_{N+1} + x_1}{\Delta S_1 \Delta S_2} \right] + \\
 & r S_{1,1} \left[\frac{x_{N+1} - x_1}{\Delta S_1} \right] + r S_{2,1} \left[\frac{x_2 - x_1}{\Delta S_2} \right] + \\
 & \left[\frac{1}{2} \sigma_1^2 S_1^2 \frac{V_{0,1}}{\Delta S_1^2} + \frac{1}{2} \sigma_2^2 S_2^2 \frac{V_{1,0}}{\Delta S_2^2} \right]
 \end{aligned} \tag{45}$$

Thus, by defining the control input associated with the boundary conditions as $u = [V_{0,1}, V_{1,0}]^T$ and one obtains a description for Equation 45 in the form

$$\dot{x}_1 = f_1(x) + c_1 u \tag{46}$$

Equivalently for Equation 44 one obtains Equation 47 (shown in Box 4).

Equation 48 is finally written in the form

$$\dot{x}_{(i-1)N+j} = f_{(i-1)N+j}(x) + c_{(i-1)N+j} x_{(i-1)N+(j-1)} \tag{49}$$

Considering that $i = 1, 2, \dots, N$ and $j = 1, 2, \dots, N$ there are N^2 state-space equations. Thus, the dynamics of the PDE model is written as

$$\begin{aligned}
 \dot{x}_{N^2} = & f_{N^2}(x) + c_{N^2} x_{N^2-1} \\
 \dot{x}_{N^2-1} = & f_{N^2-1}(x) + c_{N^2-1} x_{N^2-2} \\
 & \dots \dots \dots \\
 \dot{x}_{(i-1)N+j} = & f_{(i-1)N+j}(x) + c_{(i-1)N+j} x_{(i-1)N+(j-1)} \\
 & \dots \dots \dots \\
 \dot{x}_2 = & f_2(x) + c_2 x_1 \\
 \dot{x}_1 = & f_1(x) + c_1 u
 \end{aligned} \tag{50}$$

FLATNESS-BASED CONTROL OF THE MULTI-ASSET BLACK-SCHOLES PDE

First, it can be proven that the state-space description of the multi-asset Black-Scholes PDE, given in Equation 50, is a differentially flat one, with flat output $y = x_{N^2}$ (Rigatos & Siano, 2016). Solving the i -th row of the state space model, where $i = 1, 2, \dots, N^2$, with respect to x_{i+1} one finds that state variables x_{i+1} is a differential function of the flat output y . Moreover, from the last row of Equation 50 it holds that u is a function of the flat output and its derivatives. Next, the following virtual control inputs are defined

$$\begin{aligned}
 a_1 = & x_{N^2-1}, a_2 = x_{N^2-2}, \dots, \\
 a_{N^2-(i-1)N-(j-1)} = & x_{(i-1)N+(j-1)}, \dots, a_{N^2-1} = x_1
 \end{aligned} \tag{51}$$

Using the virtual control inputs of Equation 51 in the state-space model of Equation 50 one gets

$$\begin{aligned}
 \dot{x}_{N^2} = & f_{N^2}(x) + c_{N^2} a_1 \\
 \dot{x}_{N^2-1} = & f_{N^2-1}(x) + c_{N^2-1} a_2 \\
 & \dots \dots \dots \\
 \dot{x}_{(i-1)N+j} = & f_{(i-1)N+j}(x) + c_{(i-1)N+j} a_{N^2-(i-1)N-(j-1)} \\
 & \dots \dots \dots \\
 \dot{x}_2 = & f_2(x) + c_2 a_{N^2-1} \\
 \dot{x}_1 = & f_1(x) + c_1 u
 \end{aligned} \tag{52}$$

By examining independently each nonlinear ODE of the previous state-space description of Equation 52 and by defining as local flat output for the i -th ODE the state variable x_i it can be shown that the i -th row of the state-space description stands again for a differentially flat system. Actually, one has now N^2 subsystems, each one of them related to a row of the state-space model and the local flat outputs for these subsystems are

Box 4.

A

$$\begin{aligned}
\dot{x}_{(i-1)N+j} = & \frac{1}{2} \sigma_1^2 S_{1,i}^2 \left[\frac{x_{iN+j} - 2x_{(i-1)N+j} + x_{(i-2)N+j}}{\Delta S_1^2} \right] + \\
& + \frac{1}{2} \sigma_2^2 S_{2,j}^2 \left[\frac{x_{(i-1)N+(j+1)} - 2x_{(i-1)N+j} + x_{(i-1)N+(j-1)}}{\Delta S_2^2} \right] + \\
& + \rho \sigma_1 \sigma_2 S_{1,i} S_{2,j} \left[\frac{x_{iN+(j+1)} - x_{(i-1)N+(j+1)} - x_{iN+j} + x_{(i-1)N+j}}{\Delta S_1 \Delta S_2} \right] + \\
& + r S_{1,i} \left[\frac{x_{iN+j} - x_{(i-1)N+j}}{\Delta S_1} \right] + r S_{2,j} \left[\frac{x_{(i-1)N+(j+1)} - x_{(i-1)N+j}}{\Delta S_2} \right] - r x_{(i-1)N+j}
\end{aligned} \tag{47}$$

Equation 47 can be also written in the form

$$\begin{aligned}
\dot{x}_{(i-1)N+j} = & \frac{1}{2} \sigma_1^2 S_{1,i}^2 \left[\frac{x_{iN+j} - 2x_{(i-1)N+j} + x_{(i-2)N+j}}{\Delta S_1^2} \right] + \\
& + \frac{1}{2} \sigma_2^2 S_{2,j}^2 \left[\frac{x_{(i-1)N+(j+1)} - 2x_{(i-1)N+j}}{\Delta S_2^2} \right] + \\
& + \rho \sigma_1 \sigma_2 S_{1,i} S_{2,j} \left[\frac{x_{iN+(j+1)} - x_{(i-1)N+(j+1)} - x_{iN+j} + x_{(i-1)N+j}}{\Delta S_1 \Delta S_2} \right] + \\
& + r S_{1,i} \left[\frac{x_{iN+j} - x_{(i-1)N+j}}{\Delta S_1} \right] + r S_{2,j} \left[\frac{x_{(i-1)N+(j+1)} - x_{(i-1)N+j}}{\Delta S_2} \right] - r x_{(i-1)N+j} + \\
& + \left[\frac{1}{2} \sigma_2^2 S_{2,j}^2 \frac{1}{\Delta S_2^2} \right] x_{(i-1)N+(j-1)}
\end{aligned} \tag{48}$$

$$Y = [x_1, x_2, \dots, x_{(i-1)N+j}, \dots, x_{N^2-1}, x_{N^2}] \tag{53}$$

From the i -th row of the state-space model it can be seen that the virtual control input α_i is a differential function of the local flat output x_i , which shows again that the i -th subsystem, if independently examined, is also differentially flat.

The virtual control input for the i -th row of the state space model is chosen such that the ODE subsystem dynamics is linearized and the tracking error is eliminated. The boundary condition that appears in the nonlinear ODE subsystem that comprises the last rows of the state-space description, was used as the aggregate control input (Rigatos & Siano, 2016).

One can find the values that the virtual control inputs should have, so as to eliminate the tracking error for each one of the subsystems that are

obtained from the per-row decomposition of Equation 52. For the first row of Equation 52 one has

$$a_1^* = \frac{1}{c_{N^2}} \left[\dot{x}_{N^2} - f_{N^2}(x) - k_{p_1} (x_{N^2} - x_{N^2}^*) \right] \tag{54}$$

with $k_{p_1} > 0$, while it also holds that $a_1^* = x_{N^2-1}^*$. Continuing with the second row of Equation 52, the associated virtual control input can be obtained:

$$a_2^* = \frac{1}{c_{N^2-1}} \left[\dot{x}_{N^2-1} - f_{N^2-1}(x) - k_{p_2} (x_{N^2-1} - x_{N^2-1}^*) \right] \tag{55}$$

with $k_{p_2} > 0$, while it also holds that $a_2^* = x_{N^2-2}^*$. Continuing in a similar manner, for the i -th row

of Equation 52, the associated virtual control input is

$$a_{N^2-(i-1)N-(j-1)}^* = \frac{1}{c_{(i-1)N+j}} [\dot{x}_{(i-1)N+j} - f_{(i-1)N+j}(x) - k_{p_{N^2-(i-1)N-(j-1)}} (x_{(i-1)N+j} - x_{(i-1)N+j}^*)] \quad (56)$$

with $k_{p_{N^2-(i-1)N-(j-1)}} > 0$ where

$$a_{N^2-(i-1)N-(j-1)}^* = x_{(i-1)N+(j-1)}^*$$

By applying the same procedure, the virtual control input for the $N^2 - 1$ row of Equation 52 is found

$$a_{N^2-1}^* = \frac{1}{c_2} [\dot{x}_2 - f_2(x) - k_{p_{N^2-1}} (x_2 - x_2^*)] \quad (57)$$

Finally, from the N^2 -th row of Equation 53 one computes the boundary control input that is really exerted on the system

$$u = \frac{1}{c_1} [\dot{x}_1 - f_1(x) - k_{p_{N^2}} (x_1 - x_1^*)] \quad (58)$$

where $a_{N^2}^* = u$. Using the previous definitions, the virtual control inputs can be written as

$$a_1^* = \frac{1}{c_{N^2}} [\dot{x}_{N^2} - f_{N^2}(x) - k_{p_1} (x_{N^2} - x_{N^2}^*)] \quad (59)$$

$$a_2^* = \frac{1}{c_{N^2-1}} [\dot{x}_{N^2-1} - f_{N^2-1}(x) - k_{p_2} (x_{N^2-1} - a_1^*)] \quad (60)$$

$$a_{N^2-(i-1)N-(j-1)}^* = \frac{1}{c_{(i-1)N+j}} [\dot{x}_{(i-1)N+j} - f_{(i-1)N+j}(x) - k_{p_{N^2-(i-1)N-(j-1)}} (x_{(i-1)N+j} - a_{N^2-(i-1)N-(j-1)-1}^*)] \quad (61)$$

$$a_{N^2-1}^* = \frac{1}{c_2} [\dot{x}_{N^2-1} - f_{N^2-1}(x) - k_{p_{N^2-1}} (x_{N^2-1} - a_{N^2-2}^*)] \quad (62)$$

$$u = \frac{1}{c_1} [\dot{x}_1 - f_1(x) - k_{p_{N^2}} (x_1 - a_{N^2-1}^*)] \quad (63)$$

Stability analysis for the case of the multi-asset Black-Scholes PDE of Eq. (52) is performed as in the case of the single-asset Black-Scholes PDE. This was explained in Section “*Closed Loop Dynamics of the single-asset Black-Scholes PDE*”. In the multi-asset Black-Scholes PDE one demonstrates that the N^2 state-vector elements converge to the associated reference values. Moreover the associated Lyapunov function will be a sum of N^2 terms (instead of N).

SIMULATION TESTS

Simulation results about the proposed control method for distributed parameter systems and for the case of the single-asset Black-Scholes PDE (BSPDE) are depicted in Figure 1 (a). The spatial discretization of the single-asset PDE model consisted of $N = 25$ points. The sampling period was chosen to be T_s . The boundary condition V_{N+1} of the PDE was taken to be known and constant. Simulation examples for the case of the multi-asset Black-Scholes PDE are depicted in

Figure 1 (b) and in Figure 2(a) and 2(b). The spatial discretization of the PDE model consisted of $N = 16$ points. The sampling period was chosen to be again $T_s = 0.01\text{sec}$. The boundary condition $V_{0,1}$ served as the control input, while the boundary condition $V_{1,0}$ was set equal to zero.

The numerical simulation experiments have confirmed the theoretical findings of this chapter. It has been shown that by applying the proposed control method the single-asset and multi-asset Black-Scholes PDE dynamics can be modified so as to converge to the desirable reference profile. The control input that succeeds this, requires the recursive computation of the virtual control inputs which were defined in Section “*Computation of boundary control for the single-asset Black-Scholes PDE*” and in Section “*Flatness-based control of the multi-asset Black-Scholes PDE*”. The accuracy of tracking of the reference setpoints was indeed satisfactory. It is noted that the application of the proposed Black-Scholes PDE feedback control method is not limited to the case of option pricing but can be also extended to other financial models and indexes with spatiotemporal dynamics.

FUTURE RESEARCH DIRECTIONS

There is a wide class of problems in finance related to PDE models (Boucekine et al., 2013). There can be for instance, capital mobility and growth problems or commodities pricing problems (e.g. pricing of consumption goods, agricultural products, mining products, oil, electric power, services, etc.). In particular, it has been shown that commodities’ price dynamics is equivalent to option price dynamics, with the spot price and the convenience yield of the commodity to have a role equivalent to the one of the underlying assets that appear in the Black-Scholes PDE (Pirrong, 2014; Swartz, 1998). Therefore, one can also apply PDE control methods based on differential flatness theory for the stabilization of commodity prices. It is noted that the differential flatness theory-based control methods are of proven convergence and stability, whereas the convergent solution of optimal control problems in finance associated with the Hamilton-Jacobi-Bellman PDE can be assured only in specific cases.

Figure 1. (a) single-asset BSPDE: variation in time of the solution of the PDE at grid point x_N (blue line) and associated reference setpoint (dashed red line) (b) multi-asset BSPDE: Tracking of reference setpoint No 1 (dashed red line) by the value of the PDE system (blue line) at the final grid point $V_{N,N}$

Figure 2. (a) multi-asset BSPDE: Tracking of reference setpoint No 2 (dashed red line) by the value of the PDE system (blue line) at the final grid point $V_{N,N}$ (b) multi-asset BSPDE: Tracking of reference setpoint No 3 (dashed red line) by the value of the PDE system (blue line) at the final grid point $V_{N,N}$

CONCLUSION

First, a boundary control method for the single-asset Black-Scholes PDE has been introduced, aiming at developing an approach for the stabilization of options dynamics. Following a semi-discretization method and a finite differences scheme, the Black-Scholes PDE model has been decomposed into an equivalent set of nonlinear ordinary differential equations (ODEs) and a states-space model has been obtained. Next, it has been proven that each one of the aforementioned ODEs stands for a differentially flat subsystem. This enables to compute for each ODE subsystem, a virtual control input which linearizes its dynamics and eliminates the associated output's tracking error. From the state equations that constitute the last subsystem one can find the boundary condition that also stands for the control input to the single-asset Black-Scholes PDE model. Second, a feedback control and stabilization scheme has been developed for the multi-asset Black-Scholes PDE. It has been shown that by applying again semi-discretization and the finite differences method, the multi-asset Black-Scholes PDE can be written in a state-space form for which differential flatness properties hold. Next, the state-space description

of the system was decomposed into an equivalent set of nonlinear ODEs and a control algorithm consisting of successive (cascading) loops was developed.

To compute the boundary control input of the single-asset, as well as of the multi-asset, Black-Scholes PDE model one has to use recursively all virtual control inputs which are applied to the previously mentioned ODE subsystems. The control input of i -th subsystem becomes a reference setpoint for its successive $(i+1)$ -th subsystem. Thus computation of control inputs moves progressively from the last ODE system to the first one. Consequently, by tracing the rows of the state-space model backwards, at each iteration of the control algorithm, one can finally obtain the control input that should be applied to the single-asset, as well as to the multi-asset, Black-Scholes PDE so as to assure that all its state vector elements will converge to the desirable setpoints. By analyzing the dynamics of the closed loop system that results from the application of the aforementioned control method, asymptotic stability is confirmed.

Finally, numerical simulation experiments have been provided about the application of the proposed control method to the model of both the single-asset and the multi-asset Black-Scholes

PDE. These performance tests have shown the control method's accuracy and reliability. The method can be of interest for trading of options in open electricity markets as well as for the pricing of commodities. By showing the feasibility of such a control method it is also proven that through a selected trading policy the price of the negotiated option can be made to converge and stabilize at specific reference values.

KEY TERMS AND DEFINITIONS

Asset: A parameter in financial models which denotes a possession or a resource which can be evaluated and traded. Assets can take the form of financial derivatives (such as options and futures) or commodities or the form of equipment or other proprietary holdings.

Black-Scholes PDE: A diffusion partial differential equation which describes the dynamics of option prices. It computes the distribution of the option price as a function of time and an underlying asset variable. It can be dependent on one single asset or on multiple assets.

Boundary Control: An approach to the control of partial differential equations in which the control action is exerted to the PDE through its boundary conditions. This is different to distributed or pointwise control of PDEs, in which the control action is exerted at several points of the system's state space.

Differential Flatness Theory: A primary research direction in the area of nonlinear dynamical systems control. It considers that instead of describing the system's dynamics through its entire state vector, one can use for this purpose specific algebraic variables which are called flat outputs and which are dependent only on certain elements of the state vector. Differential flatness theory enables to succeed global linearization for complicated nonlinear dynamics and in this manner to solve the associated control and state estimation problems.

Distributed Parameter System: A dynamical system that evolves not only in time but also in space. Otherwise stated the system exhibits spatiotemporal dynamics along the time axis and along one or more spatial axes. Systems described

by partial differential equations are distributed parameter ones.

Feedback Control: The action of applying an external excitation to a dynamical system which is dependent on the value of the system's state vector and on the deviation of this state vector from a reference value that is called setpoint.

Lyapunov Function: This is an energy function of the system which depends on quadratic terms of the system's state vector error. It takes positive values apart from the equilibrium where it becomes zero. A system is stabilized when the associated Lyapunov function becomes zero.

Options: Financial derivatives which generate a secondary value for traded assets (commodities, goods, services etc.). Options are related to long term agreements about the exploitation of the traded assets so they do not reflect only the spot price of the assets but they also show the ability to accomplish the contract term's.

Pricing: The procedure of defining the price of traded assets, services or commodities. Spot pricing is an on-site agreement about the price of the traded resource based on offer and demand. There can be more elaborated pricing schemes taking place in longer time intervals (trading of financial options or commodities) which apart from offer and demand are also dependent on supporting services and procedures for the trading transaction (e.g. ability to store and transport goods, availability of equipment, credibility of the trading parts etc.).

Stability: A property of a dynamical system denoting that the state vector of the system converges to a specific point in the state space, which is called equilibrium or to a bounded region in the state-space which is called domain of attraction and remains there.

Does Inter-Bank Investments Restraints Financing Performance of Islamic Banks?

Mohammad Taquiuddin Mohamad

University of Malaya, Malaysia

Munazza Saeed

University of Malaya, Malaysia

INTRODUCTION

Interbank markets proved to play a crucial role in propagating the distress during the recent financial crisis. Unsecured financing determines clear links between creditors and debtors, stating explicitly the risk relation (Leur, 2016). If a debtor defaults, the lender's risk materializes and she has to bear the losses. Since the beginning of the financial crisis, the interbank market has been carefully scrutinized by commentators and policy-makers. It is also considered as crucial stress indicators during financial crises: they reveal not only banks' concerns regarding to the risk of financing of their counterparts, but also regarding their own liquidity needs. Accordingly, the impact of the monetary-policy measures followed by Malaysia Islamic banks, the need to look long term effect involving financing capability. Disentangling financing and liquidity effects has essential policy implications. On the one hand, if a rise in spreads reflects poor liquidity, policy measures should aim at improving funding facilities. On the other hand financing concerns should be addressed by enhancing debtors' solvency (Buigut, 2010). This question has been of utmost importance in this industry over the last few years, where most of the interbank operations conducted by Central Bank of Malaysia were designed to reduce interbank market stress. This article seeks to examine the involvement of Malaysia Islamic banks in Islamic inter-bank money market (IIMM) investment within a financing framework in dual banking

system in Malaysia. This paper also focuses on effects bank specifications, changes in monetary policy and economic environment on financing behaviour of Malaysia Islamic banks.

The article is divided into five parts. The second section describes background and performance of financing activities in Islamic banks in Malaysia. The third section, examines some previous researches and articles related with this topic. In fourth section, model and data specification adopted used in this article. The fifth section is the finding of the research. Section five and six look at the future research direction and conclusion.

BACKGROUND

Since Islamic banking was established in Malaysia in 1983, financing growth rate showed an encouraging performance. However, that performance was not consistent over the operation period of 27 years. Since there are circumstances where it is affected in economy situation. The evidence is in 1987 and 1998 when the global economy was suffering from the recession. At that time Islamic banking financing decreased from 18.36 percent to 2.68 percent. However, this situation improved and the amount of Islamic financing continued to rise for the next year since the world economy got in good condition and stable.

Table 1 shows the use of the Malaysia Islamic banking funds in aggregate in the form of several types of financing. In reference to the table, the

Table 1. Financing by type/sector

Type of Financing			2006	2007	2008	2009	2010
			RM Million

Source: National Bank of Malaysia (2006-2010)

Islamic banking financing flows are broken down into some type of overdraft financing; term financing, bill financing, trust receipts, revolving credit in foreign currencies, and the rest is represented by other available financing. During the five years of 2006 to 2010, the direction of financing flow of Malaysia Islamic banking increased around 11 to 25 percent each year with the latest financing in December 2010 making RM162,412.6 million. The majority of the total financing is contributed by the term financing type that covered financing such as leasing, financing by block, syndicate,

factoring, private financing, home financing and others. Meanwhile the least type of financing demand by the client is the trustworthy receipt¹ which only represents around 0.4 per cent from the total financing every year (Mahmood, 1997).

It should be noted, though Islamic banking offers the client interest-free financing, but the reality is the Islamic banking is still facing various form of risks especially credit risk which involves the capability of the bank to offer more financing. When this situation occurs, the bank will strive to reduce the financing volume in the future where

this will directly lead to the fall in bank's profit. Apart from credit risk, the other example of risk that could not be taken lightly is the interest risk rate which involves the existence of substitution effect where client switches to conventional bank financing due to the decrease in interest rate. This causes the financing cost in conventional bank to be much lower compared to financing cost of Islamic banking (Kader R. A., 2009).

Literature Review

In this section, the authors put forth some of past research that touched directly and indirectly on the bank's loans/financing behaviour relating to the bank's specifications, the economic environment and also the market. The review covers both local and international researchers. Hassan (1993) studied the loan sales activities of commercial banks in the United States that refers to the risks vulnerability in the capital market. To achieve the set objectives, six bank specification variables were included which are the credit variables, interest rate and also business variables. Based on five markets of risk measurement, this study found out that specification and loan expansion have a positive connection with all forms of market risk.

Hatakeda (2000) studied the banks loan in Japan under liquidity constraint from year 1975 to 1995. Researchers use estimation method of Ordinary Least Squares (OLS) towards bank sample data as well as other methods such as Augmented Dickey Fuller (ADF) unit roots test and co integration relation between variables. This study is successful in finding the empirical evidence of the existence of third regime in any bank sample that is financing under their liquidity constraint. From this regime, both land price index and bank capital have positive and great effect on bank financing. On the other hand, the call rate and economy activity (Real GDP) have a negative effect. This study also discovered how the liberation and regulation on bank capital are also influenced by bank financing behaviour.

Cebenoyan, A.S; Strahan, P.E (2004) studies on how domestic commercial bank in United States manages credit exposed risk through sales loan affect the bank capital structure, loan, benefits and also the risk from 1987 to 1994. This study use series of cross section estimation method to measure the usage of loan sales market for risk management. The study discovered bank samples balancing the financing portfolio exposure through loan trading, where bank use loan sales market as a platform in risk management and not for changing loan principal, having less capital from other bank. They produce riskier financing (*financing business*) as percentage to total asset compared to other banks. The study also discovered sample bank had a low risk and high profit compared to other bank. The study concluded that sophisticated risk management practice in banking affair increase the readiness bank credit but not fully decrease bank² risk.

Atunbas Y, Gambacorta L and Marques D (2007) studied the effect of drastic increase in security activity on banks credit offered in Europe. In this matter, the security is found to change the function of credit market by reducing fundamental liquidity role which played by financial mediator. Besides that, the variation of bank role from its original function had changed the bank capability in offering credit and bank financing channel efficiency for finance principle. This study found that the security usage protects bank financing offer from finance principle effect. In addition, bank security activity also concretes the bank capacity to offer new loan, but this capacity is dependent on business cycle condition and risk position.

Hazli and Ismail (2008) studied the effect on Malaysia Islamic banking involvement in securitisation activity towards loan/financing offer and risk tolerance level. Theoretically, securitisation activities will decrease the degree of bank avoidance risk. Thus, banks are motivated to increase the percentage of assets with a concentration of the risk through the granting of loans to economy sectors. This study refers to Islamic commercial

banks in Malaysia for years 1994 to 2004 by using the panel data analysis. The findings show significant securitisation activity cut the growth of financing. This indicates that securitisation is the replacement to the Malaysia Islamic banking financing. In addition, this study supports the *moral hazard* hypothesis where the bank involved in the securitisation will reduce financing with least risk and could do financing on riskier one.

Altunbas, Gambacorta, and Marques (2009) did an empirical research on the bank borrowing channel in accordance with European Community perspective which emphasis the role of financial innovation. This study used a dynamic model with panel data refer omg to the data of the quarter of year 1999 to the fourth quarter of 2008 in 643 banks throughout Europe³. As a result, the study found a significant relationship exists between low interest rates with risk taking by the bank, where the bank's actions have an impact on the risk of the bank. Besides that, the study also found that monetary policy is only partially neutral on monetary policy stability. Apart from that, the study also found that the banks have different lending channel especially those referring to size and credit reaction on GDP while the bank's capital is not involved in the shock transmission.

Rahman (2009) studied the relationship between the loans structure and market risk exposure of banks in Malaysia by adapting an estimation of unbalanced panel data to the eleven banks from the year of 1994 to 2006. In this study, the influence of the loans structure is analysed using four main measurements which are the properties lending, specialization index, short term loans stability and long term stability loans. In conclusion, the study found a phase of loan structure influence the level of high market risk when the financial crisis in 1997 and the year after. Besides that, bank and investors should take the effect of additional loan structure into consideration for the effect of loan expansion and management efficiency when the bank is exposed to the risk.

Sarantis and Nicholas (2009) did an empirical research on the bank loan channel for financial transmission in 8 countries of CEE (Central and

Eastern Europe), namely the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, the Republic of Slovakia and Slovenia who have joined the European Union. In this study, researchers tested whether changes in monetary policy affect bank loans which differ in the size of the bank, capital strength, liquidity and structure of ownership. To achieve the objective of the study, researchers used a method of estimating dynamic panel on bulk of the data bank panel in year 1994 to 2003. As a result, this study found that the size of the bank and liquidity has the most significant role in differentiating the reactions of banking financial policy changes. The study also looked at macroeconomic effects through bank borrowings and found evidence that linking the aggregate would lend to economic activities in CEE countries.

Kader and Leong (2009) review the impact of interest rate changes on the demand for Islamic financing in the dual system of banking in Malaysia. In their analysis, the researchers using time series on political Unit Root Test, Co integration, Vector Autoregressive (VAR), Granger Causality and Impulse Response Function (IRF) on monthly data provided by Bank Negara Malaysia (BNM) from 1999 to 2007. Several variables are included such as the total number of conventional banking financing of residential properties, the number of real estate financing Islamic banking and the base lending rate (base rate was BLR). The conclusion in this study is any increase in base lending rate (BLR) will encourage users to obtain financing from Islamic banking and vice versa.

Buigut (2010) evaluates the importance of the bank's loans financial policy transmission channel in Kenya. Loan theory stated that a strengthen financial which affect demand aggregate by moving loan supply bend to the left. This reduction may be due to the stress of the demand for loans through conventional interest rate. In explaining this ambiguity, the researchers tested loan channels by using vector error correction models (VECM) to identify supply and demand curve shifts in the market for bank loans. With this method, identification of existing problems

based on aggregate data are presented clearly. Impulse method responses also used to analyse the effects of financial policy shocks on the quantity of loans, loan rates and true output. The study found that banks in Kenya have to master all loan channels that exist.

Oliver, María Pía; Yuan Li; Jeon, Bang Nam (2010) reviewed how competition between banks influences the monetary policy transmission through loans channel of commercial banks in 10 Asian countries and 10 countries of Latin America. This study used the procedure of two-step estimation data panel from year 1996 to 2006. The first stage of the estimation is to measure the level of competition between the banks by adopting the methodology done by previous researchers. Then the next step is to estimate the equation in loan growth and included the independent variables of the bank competitor. Estimation results provided consistent evidence that the increased competition in the banking sector will weaken financial transmission policy through bank borrowings. This is true especially for banks in Latin America and small-sized banks with low liquidity and capitalisation.

Based on the above studies, researcher found a specific study related to financing institutions behaviour that it is still dominated by studies involving conventional banking and Islamic banking context where the study on these issues has yet to be done in a comprehensive manner. Existing study on Islamic banking financing done by (Kader & Leong, 2009), (Kassim & Majid, 2010) and (Rahman, 2009) are only from a different perspective and leaving literature gap that can still be filled by more research.

Model and Data Specification

The present study is based mainly on secondary data. The data and information have been collected from the publications of the National Bank of Malaysia; Handbook of statistics on Malaysia Economy and Annual reports & other valuable publications of public sector, 17 Islamic

banks in Malaysia. The period covered under the study is from 1983 to 2014. However, the period varies according to the nature of subject dealt with and availability of data. The bank-specific determinants selected for assessing impact on financing are past financing, profit, risk, capital and size of respective banks. The monetary policy changes for examining the impact on financing are money supply, Islamic Interbank Investment and investment in government securities. While the economic environment for examining impact on Islamic banks financing growth domestic product, inflation rate and index of economic freedom.

Financing model in this article adopted the approach that has been done by earlier researchers such as Hassan (1993), Hatakeda (2000), Cebenoyan, A.S and Strahan, P.E (2004), Sarantis and Nicholas (2009) by using bank annual data for viewing the response of institutional banks in offering financing. Based on the evaluation, the study proposes the following model specifications as the basis to conduct financing of Islamic banking:

$$\begin{aligned} \Delta TF_{it} = & \beta_1 + \beta_2 \Delta TF_{it-1} + \beta_3 profit_{it} + \\ & \beta_4 risk_{it} + \beta_5 cap_{it} + \beta_6 size_{it} + \beta_7 \Delta M3_t \\ & + \beta_8 iibr_t + \beta_9 mgs_t + \beta_{10} \Delta gdp_t + \beta_{11} cpi_t \\ & + \beta_{11} econfree_t + \varepsilon_{it} + u_i \end{aligned}$$

$i = 1, 2, \dots, N$ (bank amount)

$t = 1, 2, \dots, T$ (period)

where μ_{it} is the fixed effect of time, u_i is fixed effect firm and $\varepsilon_{i,t}$ is the errors term which are not serially correlate nor it correlate with all variable at time $t-1$. This study defines TF_{it} as level of financing offered by Islamic banking that covers every economic sub-sector from year 1994 to 2014. Due to the lag variable (TF_{it-1}) is independent variables in this study, the above specifications of the model developed become inconsistent. Therefore, Arellano, M; Bond, S (1991), recommended the use of estimation method of GMM which is more effective and consistent.

Table 2. Descriptive of variables statistics

Variable	Mean	Std. Dev.	Skewness	Kurtosis	Jarque-Bera
ΔTF_{it-1}	13.50	2.95	-1.97	8.80	377.44*
$profit_{it}$	0.01	0.01	-0.12	11.39	511.63*

FINDINGS

1. Descriptive Analysis

The descriptive analysis to view statistics data and variables used in the model study was formed. Some of the statistics used in determining the statistical behaviour of variables are the mean, median, standard deviation, skewness, kurtosis and Jarque-Bera. Min refers to the average value of each variable for the whole samples, while the standard deviation shows the variation of data from the mean value.

Referring to Table 2, the variable specification sample which Islamic banking has a value of cap_{it} while the largest mean has a value of $profit_{it}$ mean the smallest and least disperse in terms of the distribution of data. The summary of the statistics also showed that the total Islamic banking specification data sample skew to the left except cap_{it} which skew to the right. Kurtosis value shows the value exceeds its normal distribution where data distribution is leptokurtic shape and cap_{it} had the highest peak of 76069.98 whereas $risk_{it}$ record as the lowest value of 2.3744 that is close to normal data distribution.

For monetary policy changes variables, the distribution data shows the average value of a dispersion of $\Delta M3_t$ was the highest with the value

13.13 and mgs_{it} indicate the average value of the lowest at 3.78. The distribution data for $iibr_{it}$ and mgs_{it} is a skew to the right with the exception of data for mgs_{it} that skew to the left with 0.20. Thus the value of kurtosis for $\Delta M3_t$, $iibr_t$ dan mgs_t , all approaching the value of normal distribution respectively of 2.26, 2.97 and 2.43.

The variable of economic cycles, $econfree_t$, data indicated that the highest dispersion of data distribution is 64.60 with the value of the standard deviation of 3.63. On the other hand, the data for the variable $inflation_{it}$ indicates the lowest data distribution that is the value of 64.600 with the value of the standard deviation of 3.63. Thus the distribution data for Δgdp_t , cpi_t , dan $econfree_t$ indicates the data has skewed to the right. Kurtosis value of Δgdp_t data has less than the normal distribution which is 1.95 while the data for cpi_t and $econfree_t$ approaching the value of normal distribution with the value of each is 2.41 and 2.05 respectively.

Next test of *jarque-Bera* test was carried out to evaluate whether the data used are scattered normally or not. The results are that all data for variables used significantly at the significance level of 0.05 per cent but with the exception of data for the variable $iibr_t$. These results show that almost all the data used in this study are not scattered normal.

Table 3. Matrix correlation

	ΔTF_{it-1}	$profit_{it}$	$risk_{it}$	cap_{it}	Δgdp_t	$\Delta M3_t$	$iibr_t$	cpi_t	mgs_{it}	$size_{it}$	$econfree_{it}$

Δgdp_t	0.5481	-0.1016	0.1406	-0.1168	1.0000						
$\Delta M3_t$	0.5399	-0.1032	0.1414	-0.1070	0.9950	1.0000					
$iibr_t$	-0.4071	0.1679	0.0957	0.1016	-0.5302	-0.5427	1.0000				
cpi_t	-0.0920	0.0200	0.0912	0.0896	0.0474	0.0010	0.5557	1.0000			
mgs_{it}	-0.4197	0.1655	0.0658	0.1062	-0.5536	-0.5719	0.9905	0.5689	1.0000		
$size_{it}$	0.8859	-0.1468	0.2070	-0.2399	0.6500	0.6429	-0.4935	-0.0921	-0.5058	1.0000	
$econfree_{it}$	-0.1750	0.1896	0.1372	0.1344	-0.1535	-0.1670	0.7518	0.5499	0.7410	-0.1953	1.0000

2. Analysis of Matrix Correlation

Table 3 above shows the result of matrix correlation between independent variables (ΔTF) and other independent variables. Correlation matrix above shows the variable representing the Islamic bank specification sample which are $profit_{it}$, cap_{it} , and $size_{it}$ in relation to inverse with financing Islamic banking level, while $risk_{it}$ on positive relation. For the relationship between financial policy variables and Islamic banking financing level, the variables of $iibr_t$ dan mgs_{it} are inversely related and on the other hand $\Delta M3_t$ variable is positively related. The economic cycle variable, namely cpi_{it} dan $econfree_{it}$ has negative correlation with the dependent variables, while financing Δgdp_t relating positively to 0.548 correlations.

3. Model Estimation

Table 4 shows the estimation of a dynamic model floor financing Islamic banking. The results showed that the Islamic banking financing behaviour in this study is determined by three main factors, namely, the bank specifics, monetary policy changes and economic environment.

a. Bank Specific

Result estimation shows that lag variable of financing (ΔTF_{it-1}) shows an increase in current levels of financing and this result confirms the dynamic specifications at the level of five percent. The higher level of past financing is influenced by prudent “monetary policy” which then bring an excellent repayment track record of the customers. In addition, the past financing flow have provided in many productive sectors who are capable of generating high returns to the institution which in turn promoting Islamic banking to offer more financing for the next year.

The results also show an increase of one per cent risk level, increased the level of bank financing by 2.2700 percent. This situation reflects the Islamic banking in changing their financing portfolio by moving towards a more risky financing as a reaction to highly decreasing profit from low-risk financing. Islamic banking is generally involved in various forms of financing such as property, consumer financing, commercial financing, industrial, and others where all of which are involved in the profile and the level of risk a particular credit risks as well as other unique risks. Besides that, the effect of their active engagement in the securitisation activity also makes the bank focus

Table 4. Model estimation result

Specification	Estimation Parameter	
	GMM-Difference	GMM-System

on their assets are motivated financing risky on the factors the potential high returns (Hazli & Ismail, 2008).

In terms of capital structure, the study found an increase of one per cent of the capital structure of Islamic banking will limits the ability of Islamic banking in offering financing by -0.0020 per cent. This decision shows the Islamic banking financing and improved the provisions reducing the construction capital and this finding is consistent with research that has been done by Liu, Beng & Hua, Min, (2009) which linked the capital control of the bank (*bank capital regulations*) either a

binding or do not affect the conduct of the bank in offering financing. Rules for banks that have surplus capital, but is bound by the rules occasionally won't increase the offer of financing but also restrict the factors each financing offered resulted in an increase in risk-weighted assets ratio.

The study also shows $size_{it}$ in have a positive relation with financing with 0.7783 percent. This shows the size factor is as the main determinant of whether a bank will add financing or not. These findings are consistent with the findings of (Sarantis & Nicholas, 2009) who found the size of the bank has the most significant role in differentiating the reactions of banking monetary policy changes. (Oliver, María Pía; Yuan Li; Jeon, Bang Nam;, 2010) also found smaller banks with low liquidity and capitalisation with limited ability in offering financing/loans.

b. Monetary Policies Changes

In this section, study found only two variables, which is $iibr_t$ dan mgs_t shows the importance of the level of financing in Islamic banking. However there is a difference of the two variables where $iibr_t$ shown negative while positive sign from mgs_{it} . The negative relationship between the variable $iibr_t$ with the TF_{it} in this study showed an increase of one percent in the interbank money market investment will lead to Islamic banking reduce level of financing -0.3869 percent. These findings prove the investment activities between Islamic banks (*Islamic interbank investment*) has "substitution effect" and decreased their capability of financing because of their tendency to maintain liquidity (Othman, Ahmad, & Kechot, 1992)

While mgs_t variables showed an increase of one percent hold significant in government securities in increasing the level of financing Islamic banking of 0.4755 per cent. This shows the retention level of high government securities held by Islamic banking and sell them when enough maturity will result in high profit return as well. This returns then are distributed in the capital formation bank for the purpose of channel it into financ-

ing (ElGindi, Said, & Salevurakis, 2009). Next, growth of money supply variable ($\Delta M3_t$) indicates positive sign for financing level. These results are consistent with the theory of financing policy to link money growth increase was in line with the level of financing in bank institutions very closely with monetary policy expands. Although these results are consistent with the theory of money supply, but the study found the relationship that exists is insignificant.

c. Economic Environment

In this section, three variables included in this analysis did not indicate the importance for Islamic financing level even though the result is in line with theories and studies carried out previously. For example the variable Δgdp_t and cpi_t show negative sign while positive sign for $econfree_{it}$ variables. Insignificant of Δgdp_t in influencing financing decisions of Islamic banking in accordance with research acquired by (Hazli & Ismail, 2008) who found the Islamic banking more depending on the balance sheet indicators as a signal the economy condition compared with the general economic performance measurement.

On the other hand, one percent increase in $econfree_t$ found to increase Islamic banking financing by 0.0085%. This condition exists when economic units, especially traders and entrepreneurs have freedom and confidence doing business. Freedom means covering the freedom of doing business, trade, fiscal, investment, finance, corruption, labor and so on. The higher the level of it freedom will encourage economic units to get financing from Islamic banking which in turn contributed to Islamic banking profits (Habibullah; Sufian, Fadzman; Shah, Muzafar, 2010). On the other hand countries that have weak financial institutions such as the corruption and democracy will increase the financing problem (Boudriga, Taktak, & Jellouli, 2009)

FUTURE RESEARCH DIRECTIONS

This article showed that while the level of market domination by Islamic banks in Malaysia is still small, but the level of public confidence towards financing facilities offered by Islamic banks is always high and increases from year to year since the establishment of the first Islamic bank in 1983. This achievement can be proud of, but the strength of this credit creation they had does not mean arbitrary Islamic banking can generate any amount of financing desired restore options unless it is appropriate in order to avoid the risk of instability, especially related to subprime financing. Thus, this study presents some of the future research directions seen to conduct Islamic banking investment in interbank money market instruments:

1. Selection criterions of unproductive and high risky investment in money market instruments which will generate more profit to the bank.
2. Government's strategies through the implementation of fiscal and monetary policy as a responses of the unique features and capabilities of Islamic banking in offering financing. This research is to prevent the occurrence of shock at the industry that eventually resulted in the Islamic banking unable to react well. Failure to respond with good will ultimately upset Islamic banking into near instability in turn expose the bank to the various forms of credit risk specifically related.
3. Therefore, the future researchers can compare the patterns and performance of Islamic banking investment in interbank investment with conventional banking sector while taking other factors into account, particularly relating to fiscal developments in Malaysia.

CONCLUSION

In conclusion to, this study has discovered a pattern and behavior of the Malaysia Islamic banking financing. Based on the results, the Malaysia Islamic banking in proven extend financing taking into account the interaction between the bank's specific, changes in monetary policies and economic environment. Bank specifics involve factors of financing growth, the level of risk, vulnerability and capitalization of size. Refer to the monetary policy changes, the mechanisms of investment in government financial markets that the turned out to make an impact in determining the strength of Islamic banking credit. However, economic environment is not really a factor in influencing Islamic banking, where the Islamic banking in this study is more depended on the balance sheet indicator. It is a signal to the economic condition as compared to general measurement in performance of the economy. This study provided a limited information in relation to conduct Islamic banking in offering financing, especially in terms of samples, the use of the formulation and the variables included in the model construction research.

KEY TERMS AND DEFINITIONS

Bank Profit ($profit_{it}$): Measurement of profit before tax divided by total assets in bank. This variable indicates the number of bank profits to total assets.

Bank Risk ($risk_{it}$): Describe the results of risk-taking by banks in the appropriate timeliness. The dependence of these indicators suggest risk weights reflect the economic risks for different asset categories.

Bank Size ($size_{it}$): This ratio represents the ownership of assets by banks. High asset ownership enables banks to offer more financial services at low cost.

Capitalization (cap_{it}): Capital and reserves, as a part of the liabilities in the balance sheet total. This includes paid-up capital, reserve funds, retained earnings and other capital funds. Capital and reserves comprise own funds or a bank's core capital. More investment risk was so much more is needed capital.

Consumer Price Index (cpi_t): The relationship between the consumer price index or inflation with bank performance depends on whether inflation is expected (anticipated) or unexpected (unanticipated). In the second case (ie, inflation is not expected), the bank's actions in adjusting interest rates be the leading bank costs have increased more than the bank. This second type of inflation has a negative impact on bank profits, which in turn reduces the capital structure.

Economic Freedom Index ($econfree_t$): A ranking of countries or states based on the number and intensity of government regulations on wealth-creating activity. Metrics that an economic freedom index evaluates include international trade restrictions, government spending relative to GDP, occupational licensing requirements, private property rights, minimum wage laws and other government-controlled factors that affect people's ability to earn a living and keep what they earn. Such indexes are usually produced by economic think tanks.

Growth Domestic Product ($\Delta gdpt$): This is a key indicator of a country's macroeconomic management. Any changes in this indicator will change the loan/financing which in turn affects the adjustment capital ratio and bank risk observation for certain years.

Islamic Interbank Investment Rate ($iibr_t$): A short-term intermediary to provide a ready source of short-term investment outlets based on Syariah principle. Through the IIMM, the Islamic banks and banks participating in the Islamic Banking Scheme (IBS) would be able to match the funding requirements effectively and efficiently.

Malaysian Government Securities (mgs_t): Islamic securities that shows the loan by the government from financial institutions and others. Effectively it is a loan taken by the government of the people themselves. These loans are usually required by the state to finance recurrent expenditure and development expenditure for public projects.

Money Supply ($\Delta M3t$): Growth in money supply indicators show real growth potential, especially for future growth.

Total Financing (TF): This ratio shows the behavior of banks in the pursuit of profit and risk-taking. This behavior is consistent with profit-sharing paradigm that allows Islamic banking offer long-term financing to the project risk profile and high returns.

ENDNOTES

¹ Trust receipt is a document signed by the importer, confirming receipt of the shipping documents from the bank and allows the importer to take action on behalf of the bank to get the imported items of shipping companies. Upon receipt of the goods, the importer will be selling it and using the revenue to pay the bank.

² This study also found all of the bank specification variables are significant in relation to the risk. Capital and liquidity variables in negative relation to the risks, while credit variables in positive relation with risk.

³ Those countries are Belgium, Denmark, German, Greece, Finland, France, Ireland, Italy, Luxembourg, Netherlands, Portugal, Spain, Sweden, England and United States of America.

An Extension to the Delone and Mclean Information Systems Success Model and Validation in the Internet Banking Context

INTRODUCTION

Web-based applications in the recent years helps organizations to retain customers, and offering new services and products to them (DeLone & McLean, 1992; Tan & Teo, 2000). Internet Banking is considered as an online revolution of the traditional banking services which offers customers the greatest expediency for performing banking transactions via the Internet (Furst, Lang, & Nolle, 2000; Patnasingam, Gefen, & Pavlou, 2005). More precise definition of Internet Banking is given by Sathye (1999):

With the term electronic banking we consider all the possible transactions of a bank which are performed with the use of electronic means, mainly through Internet, but also through VPNs (Virtual Private Networks), Intranet, Extranet, phone and mobile phone, and these transactions do not necessitate that the customer must visit a branch.

There is a fundamental shift in banking delivery channels since mid-1990s (Pikkarainen, Pikkarainen, Karjaluoto, & Pahlila, 2004) and many banking executives perceived technology as the key solution for controlling costs (C.-P.

Lee, Mattila, & Shim, 2007). Internet Banking improves the bank's profit levels through the reduction of both variable and infrastructure costs, provides a source of differentiation and competitive advantage, provides global reach, adds another communication and feedback channel, increases customer satisfaction through the reduction of waiting times, thus improving service performance (Harridge-March, Wong, Rexha, & Phau, 2008). Internet Banking has appeared as the trend in banking, nowadays, and emerged as one of the payment models required to enable pure e-commerce models, rather than traditional banking (Zolait, 2010).

Some of the benefits to customers identified (Angelakopoulos & Mihiotis, 2011) are no time limitation, better time organization, no geographical limits, lower costs, 24 hour support, effortless accessibility for disabled people, integrated environment for Internet Banking transactions. In recent years, a large number of banks have started to adopt Internet Banking as an additional channel to reach and interact with clients. For financial institutions, Internet or Electronic banking is recognized as a tool that can significantly reduce their overhead costs as well as day-to-day expenses (Alhinai, Albadi, Alshihi, & Al-Gharbi, 2013).

BACKGROUND

Despite the recent advancements in internet security technologies such as, digital signatures, certificates, encryption algorithms, authentication mechanisms, consumers are still concerned about the security of monetary transactions over the internet (C. Yoon, 2010). In a report of Internet and Mobile Association of India (IAMAI -2010-11) it was found that people are hesitant to do banking transactions through the web sites of the bank, because of: security concerns (43 percent); preference for face-to-face transactions (39 percent); lack of knowledge about online transactions (22 percent); lack of user friendliness environment (10 percent); and lack of this facility in current bank (2 percent). M.-C. Lee (2009) found that the intention to use online banking is adversely affected mainly by the security/privacy risk. Hence, for the success of Internet Banking security plays a key role in customer trust of the website and satisfaction, which ultimately contribute to the success of the Information System (IS). Moreover, studies on IS Success related to Internet Banking are very scarce in the literature (Hoehle et al, 2012). Furthermore, the studies were conducted in developed countries and there is a paucity of studies in developing countries. This study intends to address the knowledge gap with the help of the proposed model. Therefore, the following research questions are framed based on the research gap:

1. What are the factors contributing to the success of Internet Banking?
2. What are the impacts security dimension make in the IB use and IB user satisfaction?

Finding the answers to the research questions can initiate improvement and enhance the performance of services provided via the electronic channel. It may also provide valuable feedback for the banks for satisfying the expectations of the bank customer, who intend to use IB in future. It is expected that this study will result in a re-evaluation of the IS Success model under new circumstances,

enhance understanding of consumer behaviors in correspondence with IB service, and provide suggestions for making sustainable IB usage. The next few sections form the literature survey of IB studies and relevant theories associated with the proposed framework.

LITERATURE REVIEW

The seminal work of Delone and Mclean (DeLone & McLean, 1992) paved the way for measuring IS success, which was elusive to researchers till then. Their (DeLone & McLean, 1992) paper proposed a six factor taxonomy in system quality, information quality, use, user satisfaction, individual impact, and organizational impact, using the multitude of measures existed in previous literatures. The authors also proposed temporal and causal relationship between the constructs.

The IS success model presumes that system quality and information quality, individually and jointly, affect user satisfaction and use. It also posited use and user satisfaction to be reciprocally interdependent, and presumes them to be direct antecedents of individual impact. In addition, the amount of use can affect the degree of user satisfaction either positively or negatively and vice versa. According to the IS Success model Individual impact should also lead to organizational impact.

DeLone and McLean (DeLone & McLean, 1992) characterize system quality as desired characteristics of the information system itself, and information quality as desired characteristics of the information product. They incorporate four scales from the Bailey-Pearson (Bailey & Pearson, 1983) instrument into system quality (convenience of access, flexibility of the system, integration of the system and response time) and nine scales into information quality: accuracy, precision, currency, timeliness, reliability, completeness, conciseness, format and relevance.

Delone and Mclean (Delone & McLean, 2003) came up with an update of their model, based on the research finding from their 1992 model. The

important change was the addition of the construct 'Service Quality' recommended by (Pitt, Watson, & Kavan, 1995). Second major change to their initial (Pitt et al., 1995) model was grouping of the two impacts constructs 'individual impact' and 'organizational impact' in to single construct 'net benefits'.

In the context of Internet Banking, customers use the IB web site to conduct money transfer, checking the account balance and pay for online e-commerce transactions, This makes Internet Banking website a communication and IS phenomenon suits itself to the updated IS success model. DeLone and McLean (Delone & Mclean, 2004) argued that the Internet applications process fits well into their updated IS success model and the six success dimensions. The authors also encourage researchers to continue testing and challenging their model. Also Research has acknowledged the need for customized measures of IS success based on the context of the system, the work process supported, and the stakeholders considered (Delone & McLean, 2003).

RESEARCH MODEL AND HYPOTHESIS

We base our work on IS Success Model (Delone & McLean, 2003). According to DeLone and McLean (Delone & McLean, 2003) 'To measure the success of a single system (individual system), 'information quality' or 'system quality' may be the most important quality component. The authors argued that for measuring the overall success of the IS department, as opposed to an individual system, 'service quality' may become the most important variable." Therefore, though service quality is important for Internet Banking, it was excluded from this study because this study is based on individual level of analysis. The next few sections describe the hypotheses of the proposed model.

HYPOTHESES

According to Chellappa & Pavlou (Chellappa & Pavlou, 2002) perceived information security is defined as the subjective probability with which consumers believe that their personal information will not be viewed, stored or manipulated during transit or compromised by inappropriate parties in a manner consistent with their confident expectations. The authors also claim that the customer perceptions of information security is influenced by encryption, protection, verification and authentication. The important empirical finding of their research is that perceived security strongly influences customer trust than financial liability of the customer. Their findings of their study support antecedents of perceived security like encryption, protection, and authentication. Kim, Tao, Shin, & Kim (C. Kim, Tao, Shin, & Kim, 2010) found positive association between users' perceived security and their use of e-payment systems. Yoon (C. Yoon, 2010) found that security in online banking strongly influences customer satisfaction. The importance of security and privacy for the acceptance of online banking has been noted in many banking studies (Chen & Barnes, 2007; Mauro C. Hernandez & Afonso Mazzon, 2007). With this, we want to test whether security features role in Internet Banking use and customer satisfaction. Hence, we propose the following hypothesis.

H1a: Security of IB website positively influences IB user satisfaction.

H1b: Security of IB website positively influences IB use.

System quality was defined as quality manifested in a system's overall performance and measured by individuals' perceptions (Delone & McLean, 2003). Since customers cannot directly interact with the bank employees directly, the system quality here is the website quality. Also the

studies (Petter, DeLone, & McLean, 2008; Petter & McLean, 2009) found strong positive association between System quality and User Satisfaction. So we propose the following the hypotheses.

H2a: System quality of IB website positively affects customer satisfaction.

H2b: System quality of IB website positively affects IB use.

Information quality perceived by the user has been instrumental in providing user satisfaction (Hirschheim, 2007; Venkatesh, Davis, & Morris, 2007). According to (Hirschheim, 2007; Venkatesh et al., 2007) the quality of information, as assessed by customers, influences their satisfaction. In the net banking scenario represents the content of the website. Information quality is considered as an integral part of customer satisfaction. So we propose

H3a: Information quality of IB website positively affects customer satisfaction.

H3b: Information quality of IB website positively affects IB use.

Delone and Mclean (DeLone & McLean, 1992) claims that use of the system (here Internet Banking website) leads to customer satisfaction and net benefits to the user. Many authors tested these two relationship with different contexts and there are moderate support for these relationships found in the meta analysis analysis (Petter et al., 2008). Hence, we propose

H4a: Use of the IB website leads to positive effects customer satisfaction.

H4b: Use of the IB website provides net benefits to the user.

We measure information systems success in the context of individual customer. Delone and Mclean (DeLone & McLean, 1992, 2003) claims that the more the user is satisfied, the net benefits is more. Here if the individual user uses more net

banking, he/she may get more net benefits. So the study hypothesizes

H5a: Positive customer satisfaction with Internet Banking usage leads net benefits to the user.

RESEARCH METHODOLOGY

Data Collection

In this study, individuals who used internet, and have experienced Internet Banking services for at least six months, were selected as research participants. We selected students of a premier educational institution in Tamil Nadu, India for this study. Students were chosen for evaluating the model because they are best suited for concept development (Sekhon, Lifan Zhao, Koenig-Lewis, Hanmer-Lloyd, & Ward, 2010). Data was collected using a printed survey questionnaire. A seven point likert type scale was employed with 1 indicating 'strongly disagree' to 7 indicating 'strongly agree' where 4 being 'neither disagree nor agree (neutral). Although we used established and validated measures in the previous studies, we developed a new dimension 'security' in the study. Hence, a pilot was conducted prior to that to ensure that there are no dubious questions. The questions were coined in such a way to avoid any technical jargons. For example instead of the question 'My bank has firewall facility', we use, 'I perceive Internet Banking provides enough protection against hacker threats'.

The participants of the survey were informed that the collected responses would be used only for research purposes. During the weeklong survey period there were 312 samples were collected by randomly visiting classrooms and obtaining permission from the respective faculty members to administer the survey. As all fields were marked mandatory and all the collected responses were verified for missing values. Students who did not answer any questions were asked to answer the same. This ensured there were no missing values.

Demographics

Out of the 312 samples 184 samples were male and 128 sample were female students accounting for 58% percent and 42% respectively. The reported age groups were fallen between 18 and 24 with the average age of 20.52. Post Graduate students were 94 and Graduate students were 218. All students have Internet Banking experience ranging from 1 to 6 years where the average experience being 2.6 years. All students reported that they own a laptop.

Measurement Development

There are six constructs in total viz. information quality, system quality, security features, use, user satisfaction and net benefits. Five items of Information quality were adapted from (Song, Baker, Lee, & Wetherbe, 2012). System quality is measured using eight items adapted from (Wang, Wang, & Shee, 2007). Net benefits has five items based on (Angelakopoulos & Mihiotis, 2011), with our own wordings.

Three measures of satisfaction were adapted from (Roca, Chiu, & Martínez, 2006). Use is measured with five variables adapted from (De-lone & Mclean, 2004; Wang et al., 2007; H. S. Yoon & Steege, 2013). Five measures of security were adapted from (Chellappa & Pavlou, 2002). Customer satisfaction was measured with five measures adapted from (Delone & Mclean, 2004; Gable, Sedera, & Chan, 2008). There are 31 items

in total representing six dimensions of our model. The proposed model is shown in Figure 1.

Exploratory Factor Analysis

Since the proposed model involves latent reflective constructs, it was proposed to conduct an Exploratory Factor Analysis (EFA). The Kaiser-Meyer-Olkin (KMO) Measure of Sampling Adequacy was 0.9, which was > 0.5 the recommended threshold. In addition, a chi-square value of 5437.719 and significance level of .000 and degrees of freedom 296, were obtained using Bartlett's sphericity test. The results clearly indicates that the inter correlation matrix contains enough common variance, justified the need for factor analysis. Hence, an EFA was conducted with SPSS 20, using Principal Component Analysis (PCA) as the extraction method, with varimax rotation with Kaiser normalization to identify the underlying factors. The PCA procedure was converged in six iterations. We deleted four items from system quality, two from information quality, two items from net benefits, due to loadings < 0.5 .

The PCA procedure was repeated again, and it is converged in five iterations. It resulted in a 22 item 6 factor structure explaining 71.9% of the variance in the model. All the items were highly loaded in their own factor (loading > 0.7) and loaded low on other factors, proving discriminant validity. In addition, each item loads on its latent factor at the significance level of 0.05, indicating

Figure 1. Theoretical model

good convergent validity. The factor loadings of the items are shown in Table 1.

TESTING THE MEASUREMENT MODEL

Reliability and convergent validity of the factors were assessed by composite reliability (CR) and average variance extracted (AVE) (see Table 2). The composite reliabilities were calculated as follows: summation of the factor loadings)/ [(square of the summation of the factor loadings) + (summation of error variables)]. The composite reliabilities were above 0.8 for our measurement

model (Table 2). Construct reliability of all the six constructs were tested using Cronbach's Alpha. The final scales of all the six constructs demonstrate high internal consistency with Cronbach's Alpha values exceeding Nunnally's (Nunnally, Bernstein, & Berge, 1967) recommendation of at least 0.7. The reliability of each factor is as follows: System quality: 0.809; information quality: 0.902; Security: 0.841; net benefits: 0.874; user satisfaction: 0.805. The Average Variance Extracted (AVE) is greater than 0.50 for all the constructs. It implies that that more than one-half of the variances observed in the items were accounted for by their hypothesized factors.

Discriminant validity was assessed, by checking whether the square root of AVE for a construct had a higher value than the variance shared between the construct and other constructs (Fornell & Larcker, 1981). The values of all diagonal elements were greater than those of off-diagonal elements (Table 3), suggesting that all of the constructs were distinct. Also the AVE for each construct is greater than the correlation between that and all other constructs. From this, it is evident that discriminant validity is proved. All the measures of reliability and validity are depicted in Table 3. Overall, the measurement model exhibited adequate reliability, convergent validity, and discriminant validity.

The final measurement model achieved an acceptable fit to the data based on a range of commonly used fit indicators. As shown in Table IV, the CFI, GFI, NFI values are all above 0.9. The RMSEA of 0.051 is below the 0.05 value thus indicating a good fit according to (Hu & Bentler, 1995) Also, the ratio of the chi-square value to the degrees of freedom is 1.824 and thus within the recommended range of 1 to 3 (McIver, 1981).

RESULTS

The Structural Equation Modelling (SEM) approach was adapted to validate the proposed structural model. SEM allows us to estimate the

strength of interrelationships between the latent constructs (Gallagher, Ting, & Palmer, 2008). The data was analyzed using AMOS Version 22 with the proposed framework shown Figure 1. The Structural model was analyzed with similar fit indices as the measurement model. All the fit indices were according to the recommended level (See Table 2). Hence, we proceed with analyzing the path co-efficient of our model.

Except for the hypothesis between use and net benefits (H4b where $B = -0.133$ and $p = 0.177$) the entire hypothesis were supported. The hypothesis with security (H1a, H1b) on use and customer satisfaction are strongly supported ($b = 0.318$ and $p < .001$, $b = 0.278$ and $p < .001$). The relationship between System quality and use (H2a) is supported at the significance level of $p < 0.01$ with $b = 0.112$. Hypothesis H2b test the effect of system quality on customer satisfaction which has a moderate support ($b = 0.103$, $p < .05$). The relationships between information quality on use

(H3a) is moderately supported ($b = 0.153$, $p < 0.05$) and customer satisfaction (H3b) has a stronger support ($b = 0.341$, $p < 0.001$). The relationships between Use and customer satisfaction (H4a) and Customer satisfaction and net benefits (H5) are strongly supported with $p < .001$ and $b = 0.035$, 0.968 respectively. The summary of the results is presented in Table 4. The percentage of variance explained (R^2) for the main dependent variable net benefits is 68%. Customer satisfaction explains 74% of the variance. Use has an R^2 value of 20%.

DISCUSSION

The purpose of this study is to test a modified IS success model by adding security as a dimension, and to study its effects on IS use and customer satisfaction in the Internet Banking context. The findings clearly indicate that security strongly influences IB use ($b = 0.437$ and $p < .001$) much more than system quality ($B = .157$ and $p < 0.1$) and information quality ($B = .224$ and $p < .05$). Perceived security has been found, to play an important role in IT adoption (Howcroft, Hamilton, & Hewer, 2002; C. Kim et al., 2010; H.-W. Kim, Xu, & Gupta, 2012; M.-C. Lee, 2009). Our study provides support for previous research, if user's perceptions about security is higher, their usage of the IB system, and satisfaction is higher. Another finding is that system quality and information quality on use ($b = 0.157$ and $p < 0.1$ and $b = 0.224$ and $p < .05$). The meta analysis by (Petter et al., 2008) found mixed support for

both these relationships. Furthermore, system quality on satisfaction ($B=0.186$ $p < 0.05$) had weak support. This is in contrast to the meta analysis (Petter et al., 2008) which found strong positive association between these relationships. The contradictory result may be due to the study (Kwon & Zmud, 1987), which emphasized that, studies on IT adoption should take into consideration, the characteristics of technology under consideration. Although we did not study adoption here, we base our study in a different context. In Internet Banking, system quality may not be an important factor for user satisfaction, because today's customer is more internet perceptive and

practical understanding of the Internet than a decade ago. In addition, our study was conducted on experienced internet users, and it may be a contributing factor for the result. Furthermore, information quality on satisfaction has moderate support in our study but found a strong support in the meta analysis study (Petter et al., 2008).

FUTURE RESEARCH DIRECTIONS

From the theoretical perspective, research should focus on the suitable replacement of the use variable in D&M model since the quality dimensions

of the proposed IS Success model has produced mixed and moderate results. Also only 20% of the variance is explained by use in our model. Seddon while specifying and validating the IS Success model (Seddon, 1997) argued that benefits from use is the only meaning of use in the D & M model. Besides this, understanding Information Systems Use (ISU) behaviors by individual users has been a tough task to {Seddon, 1997 #39} researchers and practitioners (Igarria & Tan, 1997). Also according to (Burton-Jones & Straub Jr, 2006) there is a lack of a consistently accepted definition of the ISU construct in the IS literature. The relationship between use and user satisfaction has been a point of controversy ever since DeLone and McLean proposed their model. In their modified model (DeLone & McLean, 2003) the authors explained the use construct as follows: 'Use must precede "user satisfaction" in a process sense, but positive experience with "use" will lead to greater "user satisfaction" in a causal sense'. The reciprocal relationship proposed in the studies (DeLone & McLean, 1992, 2003) has garnered moderate effects owing to the meta analysis (Petter et al., 2008). This is the focus of attention we put forth for future researchers in finding a suitable alternative for the use to overcome the limitations of the IS Success model.

CONCLUSION

Although we provide a new insight to measure IS success, the study has its own limitations. The major limitation is the context in which it is studied which is Internet Banking. The model needs to be tested in different contexts like online shopping, mobile banking in order to prove its explanatory ability. The study is conducted on students and not in public. The perceptions of a population other than students may be different. Therefore, to be considered consistent, the model has to be tested across different population. In addition, this study did not consider gender, age, Internet Banking experience or any other demo-

graphic factor, which may be relevant but not included in our study. One should evaluate this model with such characteristics to know if any differences appear in the outcome. Another key area to be considered in future research is from the perspective of the study. This study analyzed IS success from individual perspective. If it is considered from the organizational perspective (here the bankers) it may give new insights to the model, which ultimately leads to optimal use of the Internet Banking system.

KEY TERMS AND DEFINITIONS

Information Security: It is the practice of preventing unauthorized access, use, disclosure, disruption, modification, inspection, recording or destruction of *information*.

Information System: An information system (IS) is any organized system for the collection, organization, storage and communication of information.

Information Systems Success Model: Seeks to provide a comprehensive understanding of IS success by identifying, describing, and explaining the relationships among six of the most critical dimensions of success along which information systems are commonly evaluated.

Internet Banking: Also known as online banking, e-banking or virtual banking, it is an electronic payment system that enables customers of a bank or other financial institution to conduct a range of financial transactions through the financial institution's website.

Impact of Business Groups on Payout Policy in India

A

Ahana Bose

Indian Institute of Management Calcutta, India

INTRODUCTION

The presence of ‘institutional voids’ in the capital, product and labour markets of emerging economies have helped in the evolution of business groups in them. Business groups represent a unique organization structure akin to ‘cliques’ which comprises separate legally independent entities (business houses or conglomerates), working in different industries which may be unrelated in core functions, held together “by persistent formal (e.g., equity) and informal (e.g., family) ties” (Khanna & Yafeh, 2015). “Spawning” new companies by established business groups may potentially be important in emerging markets where it is probably difficult to start *de novo*” (Khanna & Yafeh, 2015). Group-affiliated firms ‘complements firm-level diversification’, reduces risk of loan default, creates internal capital markets to fund projects and aids in value creation (Classens et al., 2000). Agency conflicts in business group occur between majority and minority shareholders. The interests of managers are aligned to the majority shareholders who appoint them. Paying out regular dividends signal good health of firms to investors, but if a majority shareholder wishes to spend the same money in wasteful acquisitions then dividend payments will be irregular. Here the ‘voice’ of a majority shareholder works against the interest of a minority shareholder often forcing the latter to ‘exit’ the firm. To prevent wasteful activities of cash-rich concerns government has advocated for share repurchases through the Companies Act of 2013 in India. Nearly 30 per cent of the firms accounting for 59 per cent of assets in private corporate sector are owned by business groups

in India, one of the leading emerging economies of the world. India is slated to become the third largest economy in the world by 2030, from its 2013 rank of ten according to the estimates of a PricewaterhouseCoopers (PwC) report, which it an important market to study.

Payout policy is closely linked with most of the financial and investment decisions made by firms. It decides how much amount of cash ought to be returned by the firm to its shareholders. Payout in India occurs either through dividends or share buybacks. The challenge faced by financial economists lies in devising suitable payout policies where firms maximize shareholders wealth while investors maximize their utility. Firms in Indian corporate sector have been hoarding cash after the financial crisis of 2008-09¹. Public sector enterprises (PSU) often end up sitting on cash piles as their executives are unable to decide what to do with the excess liquidity in hand. PSUs distributed 33.1 per cent of their net profit as dividends in 2008-09, which jumped to 45.5 per cent in 2013-14. Close to 60 percent of the PSU’s hoarded cash pile is in the hands of a limited number of firms with Coal India leading the pack. Coal India had a dividend yield of 6.95 per cent in 2015.

However, it is not only the PSUs which are hoarding liquidity. The last five years have seen a dramatic rise in cash hoardings in the private sector as well. We observe that “the private sector’s cash and equivalents grew at a compound annual rate of 20 per cent, accounting for 70 per cent India’s cash pile at the end of 2013-14 compared with 52 per cent in 2007-08.”¹ While Reliance Industries have followed a miserly dividend yield of less than 1 per cent for the last five years, Piramal

DOI: 10.4018/978-1-5225-2255-3.ch005

Enterprises have had a dividend yield of 9.6 per cent in FY13. Within the Tata Group, TCS has had a dividend yield of 3.19 per cent last year and had been making regular payouts over the previous five years. On the contrary, Tata Motors, which had followed a policy of making steady payment of dividends for the last fifteen years, missed it in 2015, much to the annoyance of its shareholders.

Cairn India opting for buyback after Companies Act of 2013 belongs to the Vedanta Group while Coal India is a stand-alone company. Further Tatas, Piramal Enterprises and Reliance mentioned above constitute the top business houses in India. Probing further it is observed that Indian corporate sector has been characterized by concentrated ownership and widespread presence of business groups for a long time. The position of family owned independent trading houses strengthened after the East India Company lost its monopoly. The early 1900s, saw ethnic communities such as Tatas & Birlas gaining prominence in the economy. Post-independence, the 1950s witnessed the inception of groups like the Goenkas & Khaitans through the transfer of assets from British trading houses. The 1960s was the era of creation of groups like Reliance due to the policies of the License Raj². Later on, the economic reforms & liberalization which followed brought groups like Wipro & Ranbaxy to the forefront. Through different regimes, ownership by promoters of a business group continued to dominate the Indian corporate environment. Licensing, political connections, regulations as well as financing decisions over time have affected the functioning of business groups.

The absence of institutions in emerging markets creates difficulties in efficient resource allocation to firms. Diversified groups step in to fill the gap, aiding innovation and entrepreneurship. The goodwill of the group brand name provides a guarantee on behalf of the borrower trying to secure funding for his venture. The guarantee provided by a group's brand name (Maurer & Sharma, 2001) greatly increases its acceptability in the corporate sector due to lack of adequate screening mechanisms in emerging economies to

signal whether a borrower is a 'lemon or a plum' (Akerlof, 1995). Further reallocation of in-house talent within a business group can be done easily benefitting the new units of the group. Jones (2000) notes the similarity of BG firms to private equity ones, relating it to British trading houses in the early twentieth century. He says that one of the primary functions of these early groups was "identifying opportunities and placing potential British investors in touch with them". However not all business groups are alike. For e.g. Birla, another Indian group, "helped found and finance new firms, which were later spun-off using the entrepreneurial talent of its employees".

In the light of the above discussion the focus of the article will be to investigate the impact of a firm's ownership structure on its payout policy.

BACKGROUND

Literature reveals that one of the common ownership patterns prevalent in economies characterized with ambiguous distinction between cash and control rights is business groups. Business groups in different countries have different structures such as pyramids and clusters. *Keiretsu* groups in Japan can be horizontally or vertically integrated. *Keiretsus* can either be conglomerates constituting different industries horizontally linked through cross-shareholdings and intra-group financing or a hierarchical system of suppliers vertically integrated to the core manufacturer. *Chaebol* firms in South Korea are characterized by pyramids and cross shareholdings ownership structure. A few large, older firms present in a *chaebol* control the other firms in the group. *Pyramidal structures* finance new investments of the new firms through the existing equity holdings of the controlling group members while *direct ownership structure* deals with funding requirements through a family owner's personal wealth. Firms controlled through pyramids have lower profitability than their directly controlled counterparts and often their profits are *tunneled* away to firms where

family has higher cash flow ownership. However the underperformance of a *chaebol* is often caused by the presence of low profitability firm chosen by the family for it (selection hypothesis). Further distribution of dividends in *chaebol* appears to be unrelated to the firm's position in the hierarchy and remains unaffected even if new firms are added on to the group. The presence of "diversified business groups" describes the corporate sector of India. Inter-corporate investment plays a critical role in controlling firms of business groups Indian in sharp contrast to the ownership structures of *chaebols* and *keiretsus*.

Dearth of commensurate external funding channels often forces firms to take resort to internal funding sources to meet their investment needs. Business groups are characterized by the presence of internal capital markets. The advantage of internal capital market (ICM) over external capital market (ECM) is the former's ability to shield investment project from the information and incentive problems which plague ECM. The set up assumes the information asymmetry between principal (investor) and agent (manager/entrepreneur) is greatly reduced in an ICM as corporate headquarters (HQ) can monitor its internal divisions better than any fund provider from ECM. Corporate HQ has an internal audit system in place which increases transparency between HQ and the units, compromising the private benefits enjoyed by managers otherwise. In fact managers have to give up a portion of their private benefits to the HQ as the latter has a strong endogenous monitoring system in place to assess the manager's of a division. It curtails a manager's incentives as he is being under constant surveillance by the authority. Stein (1997) observes that better information held by headquarters relative to the external capital market aids ICMs to do a good job at picking winners, especially if the units operate in related lines of business. The flip side of ICM is that the intense competition between the divisions for corporate funding may lead to excessive lobbying (Scharfstein & Stein 2000). Collusion

between "specific divisions and the headquarters" may result in "inefficient cross-subsidizations of weak units by stronger ones". Scharfstein and Stein (2000) states that cross-subsidization of weak divisions by stronger ones in internal capital markets exhibit "socialist" tendencies. An organization often fails to discipline the weaker divisions, end up complying with their whims and compromise on the overall gains of the concern in question. Stronger divisions within the conglomerate are engaged in exerting 'productive effort' to maximize their value. They would not be keen to waste their time in unproductive work as it cuts down their profits. Weaker divisions on the other hand spend time on directly unproductive activities to increase their negotiating power with the headquarters in the subsequent period.

Business groups have evolved in economies where incomplete capital markets and inefficient labour markets. In such cases presence of internal capital markets generated within the business groups help in efficiently allocating resources and filling up the "institutional voids" created by both them in the economy (Khanna et al. (2005). Vig (2013) discusses how strengthening of creditor rights through SARFAESI Act reduces depositor confidence leading to liquidity hoarding in India. Excess in-hand liquidity plays a crucial role in deciding payout strategy. Gopalan et al. (2014) states that group firms payout significant amount of dividends despite agency problems and weak enforceability of legal regulations in the economy. The propensity to do so is higher if group members possess attractive investment opportunities which require immediate funding.

Table 1 illustrates how assets are distributed across the sectors and over the years according to ownership criteria. We find that business groups (BG) owns majority of the assets the in Manufacturing and Non-Financial Services while the opposite holds true for the electricity and mining sectors. We also observe that the amount of assets held by BGs has increased significantly over the years.

Table 2 illustrates how cash in hand is distributed across the sectors and over the years according to ownership criteria. We find that BG has higher cash balance than Non BGs in Manufacturing, Non-Financial Service and Electricity sectors while Non BGs hoard higher cash balances in the Mining Sector. Presence of abundant free cash in the firm may lead to overinvestment of funds.

One of the critical decisions of a firm with excess liquidity in hand is fixing up its payout policy. Payout policies are intrinsically related to the financing and investment decisions of a firm and should be decided with foresight and care. The repeated nature of payout decisions implies managers while deciding it need not only keep in mind the pecuniary aspects but also the long-term reputation of their organization. A conservative

board favors high dividend pay outs while a liberal school of thought espouse stock repurchases. Some board members are indifferent to the choice between dividend payouts and repurchase thinking it does not affect value of the firm.

There has been limited research on the impact of the organization structure of a firm on internal liquidity management in Indian context. Dividend payments and share buybacks are manifestations of what a firm does with excess cash. The next section provides an overview of the payout policies followed by the cash-rich firms in India in recent times.

OWNERSHIP STRUCTURE AND PAYOUT STRATEGY

Firms in India, belonging to business groups typically have a dominant shareholder. Hence, the chance of pursuing entrenchment strategies by them is quite high. Managers of such firms sometimes often carry out activities which render them indispensable to the firm in question. For example, they may follow investment policies designed to suit their needs without bearing in mind the welfare of the shareholders of the company. When managers enjoy private benefits through control, they may exhibit a tendency to smooth dividends. During a downturn, they are likely to pay high dividends to increase their tenure. On the better days, their short term gains bother them less. Following a stable payout policy helps firms to obtain easy access to the capital markets. When firms hold on to an excess amount of cash, then regulators of the economy often mandate share buy-backs to reduce a firm's outstanding number of shares in the market.

Ownership Structure and Dividend Payout

Dividend payments are strongly associated with the reputation of a firm. If a firm has made a bad investment and lost money then it will be finan-

cially constrained and unable to payout dividends to its shareholders. It does send a negative signal regarding the firm's health by its inability to pay dividends on time. However if the firm has a long-standing reputation for making on time dividend payments then stockholders may consider the firm's misfortune in its new investment and allow it time to recover its financial health. Lintner's (1956) analysis about a firm's decision regarding dividends provides a behavioral perspective to the dividend payout story. The survey states most companies while deciding its payout strategy follows a target payout ratio, ensure that dividends lag earnings and try not to vary dividend payment amount much. However Hail et al. (2014) states that payout policies are altered due to information shocks. Miller (2015) explores the effect of financial crisis of 2007-08 on payout policies.

Analyzing aspects of taxes, asymmetric information, incomplete contracting possibilities, and transaction costs embedded in the assumption of perfect capital markets enriches our understanding of the form and pattern of payout policies of corporations. The event of coming together of stockholders of companies with dividend policies aligned to their preferences is called the clientele effect. Clientele effect can be classified into static and dynamic ones. Static clientele models deal with different groups, or "clienteles" who are taxed differently. Miller and Modigliani (1961) argued that "firms have an incentive to supply stocks that minimize the taxes of each clientele. In equilibrium, no further possibilities for reducing taxes will exist and all firms will be equally priced." Dynamic clientele model rests on the premise that if investors continue trading activities over time then tax liabilities are likely to be reduced. Those who are taxed the least will get the dividend paying stock. However such trades may get reversed after the ex-dividend paying date. Jensen et al. (1976) observe that the managers of a publicly held firm can allocate resources to activities which may benefit them, but may not be aligned with that of the shareholders. Instances of such activities can range from excessive expenses

Table 3. Dividend distribution over the years

Year	Mean of Equity Dividend as a Percent of PAT		Mean of Preference Dividend as a Percent of PAT	
	BG*	NON_BG**	BG	NON_BG
2004	14.75	9.07	1.23	0.30
2005	15.81	9.82	1.61	0.29
2006	12.53	8.80	0.52	0.29

on corporate parties to unnecessary takeovers. Presence of abundant free cash in the firm may lead to overinvestment.

Payment of dividends can be in the form of cash or stock. Stock dividends are akin to bonus shares which are equivalent to a stock split. They increase the numbers of outstanding shares, reduce the price per share yet the company's assets, profits and the total value stays unaffected. There are regular dividend payments paid out at annual, semi-annual or quarterly time intervals as well as special dividends paid in addition to regular ones. VSNL, an Indian concern offered its shareholders a special dividend of 450 per cent before it went in for disinvestment in 2001.

Dividend payments in India before 1997 were subject to double taxation. Not only were the companies declaring dividends taxed but also the shareholders receiving dividend payments were subject to tax payment by the government. After 1997, the rules were changed, and firms issuing dividends were the only ones required to pay taxes. 2002-03 Budget reverted to the old double taxation policy for dividends. However, 2003-04 Budget changed the dividend distribution tax policy to what it had been after 1997.

Currently, firms paying dividends need to pay 16.9 per cent of dividend distribution tax to the government in India.

Dividends signal the health of a firm to the market. Majority shareholders may use dividends as a disciplining mechanism to keep their managers in check as enforceability of contracts is low in India. However in a family owned firms' agency issues between majority shareholders and managers are secondary in importance, as most of the managers are personal appointees or family members of the former and are unlikely to jeopardize their relationship with them. As the boundary between cash and control rights is fuzzy in business groups, and opaque to an external observer it is well-nigh impossible to comment on the nature of coordination between a manager and an owner while deciding dividend payout policies.

Table 3 describes the distribution of dividends as a proportion of profit after tax. Equity dividends are more popular than preference dividends in India. The data in Table 3 clearly indicates that BGs are more committed to paying out dividends than NON_BGs. However, there are instances where BGs have defaulted on their dividend payments. For example, when Tata Motors missed their divi-

Table 4. Distribution of equity dividends over the years in NON_BG firms

Year	Mean of Equity Dividend as a Percent of PAT				
	Govt*	Foreign	Indian Private	Joint Govt & Private	Stand Alone
2004	16.10	19.77	8.04	24.05	3.01
2005	13.68	19.70	9.05	14.51	6.46
2006	15.35	20.16	7.79	19.67	13.51
2007	12.54	14.23	7.36	51.41	5.47
2008	12.56	16.95	7.33	9.87	11.24
2009	12.37	14.98	8.46	14.93	5.20
2010	12.67	18.17	6.20	11.66	11.01

dend payment in 2015 for the first time since 2001, it greatly annoyed its aged shareholders; as it was the primary source of income for many of them.

Table 4 illustrates that within NON_BGs the enterprises owned by foreign private sector pay out the maximum dividends, followed closely by Government-owned firms. The firms under the joint ownership of Government and Private sector dole out large dividends as well. In fact, relative BG owned firms, firms under foreign ownership; government owned as well as joint ownership pay out a larger quantity of dividends. However as the standalone entities and privately owned firms pay fewer dividends than the firms under foreign ownership, government owned as well as joint ownership, the mean dividends paid out by all NON_BG firms taken together appear to be less than BG firms.

Ownership Structure and Share Repurchases

The debate between whether to pay out dividends or buy back shares has raged on for a long time. A fundamental difference between the two modes of payout policy is that while dividend payments

are expected to be stable payments over time, stock repurchases may be one-time occurrence for a firm. However, there are a fair number of investors who would prefer firms to buy back their shares rather than pay out dividends.

Repurchases help to do away with free cash flow problems and mitigate conflicts between insiders and external investors. Decisions about repurchase of shares rather than opting for an increase in dividend is positively related to executive options while the number of shares bought back positively correlates to the number of exercisable options (Kahle, 2002). Reddy et al. (2013) state that share repurchases in India assure short-term returns but result in low price earnings ratio compared to pre-buyback period. Gasper et al (2012) state that undervalued firms often signal their value through repurchases. However firms held by short-term investors opt for repurchases more often as they care strongly about the short-term price reaction.

Indian companies went for a total of hundred and sixty buyback offers during 2004-11, out of which only sixty-seven were tender offers. Rest of the buy-back offers happened through the open market route. The Company Act of 2013 explic-

Table 5. Comparison of share repurchases and dividends paid over the years

itly stated that firms sitting on cash piles ought to buy back their shares to reduce the number of outstanding shares in the market. Post the announcement instances of share repurchases have gone up in India.

Table 5 clearly shows that after 2013 share repurchases have increasingly becoming popular post 2013 among the non-business groups (NON_BG) in India. Whether buybacks will replace dividends in near future in India is yet to be seen. The crisis years of 2008-09 saw BGs indulge more in share repurchases than NON_BGs. The erratic pattern of share buybacks is in stark contrast to the mean amount of dividends paid out over time. We find that a number of dividends proposed and paid out have risen steadily over the years for both BGs and NON_BGs.

FUTURE RESEARCH DIRECTION

Carrying out a detailed comparative analysis of payout strategies, tunneling of profits in other emerging and developing economies can be an insightful study. Whether “peer effect” of the corporate HQ affects the payout strategy of its subsidiaries needs to be probed in near future to

help researchers understand how group dynamics impact key decisions in corporations.

CONCLUSION

Business groups dominate the corporate landscape in India. They are found to favor dividends to share buybacks as a payout method. Possibly the notion that share repurchases destroy the value of a firm may encourage them to do so. Share repurchases drive up stock prices, which often cannot be sustained in the long run. At times it adversely impacts the credit rating of the firm and impedes its access to finance. The clientele effect may play a crucial role in deciding the payout policy of firms. While boards of business groups constitute primarily of family members, stand-alone firms have people appointed on professional merit. As a result the latter is more open to experimenting with financing and investment policies. Of late, the stand alone firms are increasingly opting for share repurchases to strengthen their control in them.

Since 2002, firms in India are financializing; i.e they are diverting a substantial part of their cash holdings to the financial sector instead of investing the funds in expanding their production

capacity. Rather than utilizing the excess cash in hand to pay out dividends firms opt for projects where payoffs are realized within a shorter time span. Firms use the cash in hand to purchase financial instruments for getting quick returns instead of investing in long term projects hindering the existence of the firm in the long run. Though group owned firms have exhibited high incidence of financialization (Ganguly & Bose, 2015), yet they have been steadily paying out dividends as well. Whether financialization can be sustained along with a steady payout strategy and how it affects the latter over time remains to be seen.

In general, the chapter addresses the question of how the excess cash in hand of managers of conglomerates gets transferred to the shareholders through payouts. However if a firm believes that liquidity hoarding can strengthen its position in product markets and provide it a strategic advantage in becoming a market leader then they may withhold payouts. Currently, research findings in the aforementioned domain are inadequate; sufficient scope exists in delving into the same to understand how conglomerates influence the functions of corporations.

Noise Trader

A

Po-Keng Cheng

State University of New York, Stony Brook University, USA

INTRODUCTION

Let us start with differentiating between *noises* and *shocks*. While the two terms have some differences, they share some characteristics. Shocks are unexpected large events that affect an economy, while noises are the aggregation of small events which could have powerful influences on the market than a shock can be. Noises and shocks both result from uncertainty and have certain influences on the financial market. Their differences are notable however. Information about shocks is available to everyone in the market but information about noises is not. For an example of a shock, suppose there is an earthquake in Antarctica. Noises, in contrast, come from information asymmetry. For instance, a trader receives messages of an acquisition for company alpha from a manager in company beta, but other traders in the market do not receive the information. Although the information could be wrong, the informed trader who receives the messages will buy more stocks of company alpha in the market. The sudden increase in the demand of company alpha's stock triggers the price of its stock rising sharply, which creates a noise.

Before the shocks happen, traders assign probability measures of shocks and consider their impacts when making financial decisions. Suppose all the traders in the market are fully rational and the initial allocation is Pareto-optimal, then the private information observed by a trader would not cause trades (Milgrom & Stokey, 1982). Thus, the existence of noise trading would provide liquidity to the market (Black, 1986; Dow & Gorton, 2008). However, observed market crashes, such as the Black Monday in 1987 and the burst of Dot-com Bubble in early 2000s, raise the questions whether

all the traders in the market are fully rational and markets are efficient.

BACKGROUND

Lucas' asset pricing model (Lucas, 1978) suggests asset prices are the discounted value of dividends with time preferences. The asset price p_t^e (Krusell, 2007) is equal to

$$p_t^e = E_t \left[\sum_{s=t+1}^{\infty} \beta^{s-t} \frac{u'(y_s)}{u'(y_t)} d_s \right],$$

where β represents for consumer's time preference, $u'(\cdot)$ is consumer's marginal utility function, y_t is the endowment consumer received at time period t , and d_t is the dividend asset paid at time period t . But in the real world, the fluctuations of asset prices in the financial market are far greater to be explained by changes in dividends (Shiller, 1981), suggesting the asset prices are affected by more than fundamentals (Shiller, 2003).

Harrison and Kreps (1978) argued that heterogeneous expectations on dividends policy may cause the price of stock to differ from its fundamental value. De Long, Shleifer, Summers, and Waldmann (1990b) provided a theoretical basis for the noise trader approach. They proposed that the existence of noise traders could lead to divergences between market prices and fundamental values. Additionally, they suggested that some financial anomalies, like the excess volatility of asset prices, the mean reversion of stock return, and the equity premium puzzle could be explained by noise trader risk. Another paper (De Long,

Shleifer, Summers, & Waldmann, 1990a) by the same authors suggested that with the presence of positive-feedback investors, rational arbitrageurs' early positions trigger positive-feedback trading which drives asset prices away from fundamentals. Cutler, Poterba, and Summers (1990, 1991) formalized the role of feedback traders and presented evidences on the characteristic speculative dynamics of returns across markets. Frankel and Froot (1990, 1991) proposed the forecast models of chartists and fundamentalists in which portfolio managers place different weights on chartist and fundamentalist views, explaining the appreciation of the US dollar in 1981–1985.

The noise trader approach (Shleifer & Summers, 1990) aims to explain the equity premium puzzle and other phenomena which cannot be explained well by efficient market hypothesis. There are two main assumptions in noise trader approach. First, not every investor in the market is fully rational: noise traders' demand for assets is affected by their beliefs or sentiments. Second, the limits of arbitrage prevent fully rational investors from bringing the price back to fundamental values. The existence of noise traders may drive out rational arbitrageurs in the market and create positive returns. Shleifer and Vishny (1997) mentioned that with the existence of noise traders in the market, rational arbitrageurs may avoid high volatile positions, dampening the effect of arbitrage which brings prices back to fundamental values.

FUTURE RESEARCH DIRECTIONS

Given the theoretical background of noise traders, the remaining question is how to reveal noise traders in real data. This section introduce several studies related to noise traders from different approaches.

Heterogeneous agent models (Hommes, 2006; LeBaron, 2000, 2006, 2012) consider agents being boundedly rational and following heuristics

or rule of thumb strategies, where the models generate stylized facts, such as clustered volatility and fat tails in asset returns, in the financial market. Several studies since 2005 have focused on estimating the parameters of these models and comparing estimated findings to that of observed historical data (Alfarano, Wagner, & Lux, 2005; Boswijk, Hommes, & Manzan, 2007; de Jong, Verschoor, & Zwinkels, 2010).

Baker and Wurgler (2006, 2007) formed a composite investor sentiment index, where the investor sentiment has significant effect on capital market prices. They found that small stocks, young stocks, unprofitable stocks, high-volatility stocks, non-dividend-paying stocks, extreme growth stocks, and distressed stocks tend to be disproportionately sensitive to broad waves of investor sentiment. When the sentiment is low, these stocks earn relatively high subsequent returns. On the other hand, when the sentiment is high, their subsequent returns are relatively low.

Barber, Odean, and Zhu (2009a, 2009b) analyzed trading records for 66,465 household at a large discount broker and 665,533 investors at a large retail broker and documented that buying and selling decisions of individual investors are highly correlated and persistent. In addition, retail trade imbalances forecast future returns. Over short horizon, such as a day or a week, stocks heavily bought by retail traders earn strong returns, while stocks heavily sold by them earn poor returns. However, over annual horizon, the retail trades move only the prices of small stocks in the same direction of their trade.

Bloomfield et al. (2009) distinguished noise traders from informed traders and liquidity traders, and designed a laboratory market to investigate the behavior of noise traders and their impact on the market. Their results indicated that noise traders have positive effects on market liquidity, acting as rational liquidity providers or behavioral contrarian traders. However, the presence of noise traders adversely affect the informational efficiency of the market when informed traders hold very valuable

information. Moreover, a securities transaction tax would not only limit noise trading, but also reduce the trading and profitability of informed traders.

Expectations of returns are investors' beliefs about future stock market returns, while expected returns (ER) are propositions by financial economists in which the measures of ER are computed by aggregate variables, like dividend-price ratio, consumption, and interest rate. Greenwood and Shleifer (2014) analyzed investor expectations of future stock market returns from six survey data source between 1963 and 2011 and measured ER by dividend-price ratio and variables proposed by Campbell and Cochrane (1999) and Lettau and Ludvigson (2001). The six measures of expectations are highly positively correlated with each other, positively correlated with past stock market returns and the price-dividend ratio, and also highly correlated with investor inflows into mutual funds. Both expectations of returns and ER predict future stock market returns, but ER and expectations of returns are negatively correlated with each other. These findings contradict rational expectations models, in which expectations of stock market returns and model-based measures of ER should be perfectly positively correlated. They reconciled their evidence with the earlier class of behavioral models developed by Cutler et al. (1990) and De Long et al. (1990a), in which fundamental traders require a premium to accommodate the time-varying demand of extrapolative traders. Barberis, Greenwood, Jin, and Shleifer (2015) developed a heterogeneous-agent consumption-based model with two types of infinitely-lived traders: extrapolators and rational traders. The extrapolators extrapolate the market's past prices changes to form their price beliefs, while the rational traders are fully rational and have correct beliefs about the evolution of future stock prices. Their model captures several features of actual prices and returns, such as the excess volatility of stock market returns and the predict power of price-dividend ratios for future price changes.

CONCLUSION

The efficient market hypothesis and the CAPM model indicate that the demand curve of stocks in the financial market would be flat. Some research had worked on figuring out the slope of demand curve for stocks in the market, such as Shleifer (1986). If the efficient markets hypothesis holds, the demand curve of stocks would be flat because all investors agree that the prices of stocks equal their fundamental values. However, this does not exist in the real world: the investors agree to disagree. Thus, an alternative approach to explain the price movements in the financial market is necessary. Challenges faced in related research to noise traders are collecting data on investors' behaviors and distinguishing between different types of traders (Khandani & Lo, 2011; Nagel, 2012; Lou, 2012). However, from the biographies of successful investors and speculators together with the studies introduced above, we could conclude that investors are not fully rational in the market and extrapolative traders do play a role on the price fluctuations in the financial market.

KEY TERMS AND DEFINITIONS

Agree to Disagree: A question discussed in Aumann (1976). If two agents have the same priors and their posteriors for an event are common knowledge, then these posteriors will be the same. That is, these two agents cannot agree to disagree.

Common Knowledge: An event E is common knowledge if E is known by each agent in a group, if each agent knows that E is known by each of them, if each agent knows that each agent knows that E is known by each of them, and so on.

Equity Premium Puzzle: A phenomenon observed by Mehra and Prescott (1985) that the average returns of equity are higher than those of

Treasury bills in the U.S. data during the period of 1889 to 1978.

Fully Rational: Agents who are rational with common knowledge that equilibrium trade is feasible and each agent is rational.

Fundamentalist: Traders who believe the existence of fundamental values and trade based on their expectations of fundamentals.

Heterogeneous Belief: Agents have different expectations for the state of future. Traders with heterogeneous beliefs have different price beliefs for next periods' prices in the financial market.

No-Trade Theorem: Suppose traders in the market are risk-averse and fully rational. If the initial allocation of resources is Pareto-optimal, then private information received by an individual trader will not cause trade, see Milgrom and Stokey (1982) for more details.

Pareto-Optimal: A feasible allocation is Pareto-optimal if there is no other feasible allocation which makes some individuals better off without making some individuals worse off.

Positive-Feedback Investor: Traders who buy when prices rise and sell when prices fall.

Rational: Agents who have von Neumann-Morgenstern preferences.

Safeguarding of ATM

INTRODUCTION

In today's world ATM has become an inevitable part of human's life. All the developing countries are spending a lump sum of money in printing their currencies and to recycle it. Therefore, the world is changing towards cash-free transactions (Ray, 2015). Cash-free transactions can be done in various ways (PaymentWall Blog, 2015), among which plastic cards plays a vital role. According to (Sharad Raghavan.T.C.A, 2015; Hemali Chhapi, 2015), the cost of printing a currency note is much higher than that of its face value. Rather than spending a huge amount in printing and recycling notes, the cost of preparing plastic cards is considerably less. Hence in order to promote plastic cards as the primary mode of fund transfers, the banking sectors has introduced credit cards, debit cards, etc., throughout the world. Banks provide a number of card systems to facilitate and to attract the customers (BankBazaar.com). It is estimated that the number of ATMs have been increasing every year (Diebold, Incorporated, 2012; Statistic Brain, 2015). Henceforth, security to safeguard ATM in all aspects has become an inevitable one. In this article, a hybrid model consists of both logical and physical ways of securing has been suggested.

BACKGROUND

An ATM is Kiosk machine which has been filled with cash of various denominations, where the person can withdraw money at any time, by using the plastic card. That plastic card has been given by the bank from where the person is having his/her account. That card has a magnetic stripe, a 16 digit card number, a Card Verification Value (CVV) and a 4 digit secret pin which helps the customer to withdraw the amount. Now-a-days, our Indian Government insists all the citizens must have an account in a bank and immediately a debit card has been given for it, thereby promoting cashless transactions. Hence it is mandatory to provide security features for an ATM (Diebold, Incorporated, 2012). Once a card has been issued, the banking sectors are insisted to place Automated Teller Machine (ATM) at various places throughout the country for the benefit of the people (BankBazaar.com). Many research works have been done in providing security for the kiosk machine. But, as per the Newton's Third law *For Every Action there is an equal and opposite reaction*, the more security researchers found, the more techniques were being followed by the robbers to steal the money from the ATM (Diebold, Incorporated, 2012). Kiosks placed within business areas are considerably safer and are less prone to get robbed (McGoey, 2015). Robberies are done by targeting

free standing ATMs in the high ways (McGoey, 2015). Several techniques are used by robbers to steal cash, some of them are card/currency fraud, logical ways and hard ways of attacks (Diebold, Incorporated, 2012; Wild.O, 2015).

Card and currency fraud includes skimming, Transaction Reversal and card/currency trapping/phishing. In these techniques, the perpetrator would fix an extra device to an existing ATM and tries to grab the customer's confidential data thereby steals the money from their account.

In logical attack, the robbers attempt to grab the confidential data of the customers, in a smart way. In 2015, the malware attack is the most common logical attack, in which the perpetrator injects a virus called Tyupkin. The infected ATM will be then work under the control of intruder.

The physical attack is one, in which the robbers target the ATM and try to break it by drilling, cutting, and using fire exposures / explosives. Even, it includes pseudo ATM placement, removal of the ATM, smashing the ATM and many more. In some cases of logical and fraud methodology also, burglary is done by using partial breaking of the machine. Malware is a type of logical attack, in which a partial physical attack is implemented to open the top hat of ATM to inject the malware. Therefore, in any ways the ATM is disturbed by physical attack (Kaspersky).

Although several researches outcomes have been implemented to prevent and detect the ATM frauds, the physical attack on ATM is still increasing (E.A.S.T, 2016). The survey (SecureWorld, 2016) says the percentage of Physical Attacks on ATM is increased in a drastic way. According to European ATM Security Team (EAST), in the year of 2015 alone about €49m was stolen by hard breaking of around 2,657 ATMs (E.A.S.T, 2016). This is because; the main target of the looters is to grab the cash dispenser within a short duration.

There are several detection technologies and risk management technologies available that can expose attacks only after the money is gone (Peter

Beardmore, 2016). So it is indeed not only to detect but also to safeguard the ATM from the intruders.

MAIN FOCUS OF THE ARTICLE

Here, in this article, the primary focus is mainly on safeguarding ATM from physical attacks and how it can be prevented by using a hybrid model.

1. Types of Attacks

The highest rate of ATM fraud was recorded in the year of 2015 (Kelley Moody, 2016). Following section discusses in brief the various types of physical and partial physical attacks on ATM throughout the world.

1. **Ram Raids:** The primarily used hard ways is this, in which the ATM is totally removed from its location with the help of truck or large vehicle. The robbers choose this type, as its success rate is very high, with no extra knowledge or effort (Deluca.R, 2012).
2. **Cutting:** It is another type of physical attack, where the criminals use tools like scissors, saws, screwdrivers, to open the safe door or to break the safe wall of the ATM (Diebold, Incorporated, 2012; Deluca.R, 2012).
3. **Plastic Explosives:** Another foremost type is that robbers are making use of plastic explosives or small dynamites to break the lobby. Such kind of dynamites once ignited can be suppressed by using the method suggested by (Staines.B, 2012). In case of cutting, the Kiosk machine alone gets damaged, whereas in other two methods, there is a possibility of demolishing the outer surroundings also.
4. **'Black Box' Attack:** In a black box assault, the crooks gain physical access to the top of the cash machine. From there, the attackers are able to disconnect the ATM's cash dispenser from the "core" (the computer and brains of the device), and then connect

their own computer that can be used to issue commands forcing the dispenser to spit out cash. In this particular attack, the thieves included an additional step: They plugged into the controller a USB-based circuit board that NCR believes was designed to fool the ATM's core into thinking it was still connected to the cash dispenser. NCR says the crooks then attached a smart phone (a virgin, out-of-the-box Samsung Galaxy 4), which they used as a conduit through which to send commands to the cash dispenser remotely (Brian Krebs, "KrebsonSecurity", 2015).

5. **Wiretapping ATM Skimmers:** "In this attack, the ATM fascia is penetrated close to the card reader to create a hole large enough for the attacker to reach inside the ATM and place a tap directly onto the card reader in order to skim card data as it is read by the ATM," NCR (National Cash Register) said in an advisory it produced on the increasingly common attacks (Brian Krebs, "KrebsonSecurity", 2014). According to NCR, the emergence of this type of skimming attack is a response to the widespread availability of third party anti-skimming technology which is successful at preventing the operation of a traditional skimmer, placed on the outside of the ATM (Brian Krebs, "KrebsonSecurity", 2014). NCR observed that crooks employing this attack are using a variety of methods to create the hole in the front of the ATM. Modern ATMs often now include sensors that can detect vibrations consistent with drilling or cutting tools, so some thieves have taken to melting the ATM fascia in some cases. "Melting techniques have been observed which can circumvent seismic anti-drilling sensors," NCR said. According to quarterly reports from the European ATM Security Team (EAST), ATM "attacks in which the fraudsters attempt to blast open the machine with explosive gas are on the rise". "Collateral damage for solid explosive attacks is a major

concern. In one country, the average overall frequency of ATM related physical attacks is five incidents per week. Three countries reported significant collateral damage from physical attacks, in addition to cash losses suffered (Brian Krebs, "KrebsonSecurity", 2014)."

6. **Spike Brutal ATM Attacks:** (Press Trust of India, 2013, November 22), A study by the industry chamber revealed that ATMs across the country are facing a massive shortfall of 1.5 lakh security guards. Of around 1, 25,000 ATMs in the country, only 50,000 are guarded and just 1.15 lakh are covered by CCTVs, the study found. "The shocking incident at Bangalore underscores the need for recruitment of the guards at expeditious speed to ensure that all the ATMs are properly guarded and equipped with security gadgets, other than CCTVs," it says. A woman employee of Corporation Bank was attacked brutally at the on-site ATM of the bank. After entering the ATM booth and rolling the shutter down, the assailant attacked the woman when she refused to draw money and hand it over to him. "While recruitment of guards and manning ATMs 24X7 may be a time-consuming and costly affair, the answer lies in using hi-tech security gadgets like automatic alarms, improvement of camera footage and setting up central monitoring rooms for coordination between banks and the police," the study said.

2. Materials and Methods

Many tools are developed by several firms to deter Smash and Grab attack on ATM. Subsequent section discusses about the widely used tools that are under implementation.

1. **ATM Plinths:** As per (SCOTIA - Security Group) The Universal ATM Plinth ensures rapid installation, relocation and removal of all ATM models. The patented telescopic

design permits assembly in minutes within a huge height range with no wasted components, while micro-fine adjustment allows for extremely uneven floors. The plinth can be adjusted whilst the ATM is attached, thus negating manual handling issues and allowing the advantage of transportation via pallet truck. These factors allow quick installation and dramatically reduce site times and associated costs.

2. **ATM Pods:** (Associated Security Solutions, 2016) ATM pods provide an added layer of security for the ATM and staff during Cash In-Transit deliveries.
 - a. A bespoke ATM pod made to specific customer sizes depending on number of ATMs housed.
 - b. The unit is 5 sided consisting of wall & roof panels that can be installed easily on site.
 - c. Available with variety of locking options - key, combination, digital and biometric locks.
 - d. Handle and lock on inside for added security when loading ATMs.
 - e. Option of interlock between main door and ATM doors.
3. **Locking Bars:** (Associated Security Solutions, 2016) – “Our Sophisticated interlocking bars ensure that no more than one door can ever be opened at the same time whilst replenishing the ATM. ATMs are often the weakness in many Retail Banking outlets. They hold high volumes of cash and in most instances they are located in the exterior of the building making them an easy target for attack. Our inner locking bars are comprised of a set of four interlocking doors connected by a sophisticated electronic locking system that ensures that no more than one door – accessing one of four cash cassettes – can ever be open at the same time. Once closed, no door can be reopened until a pre-set time has elapsed”.

4. **ATM Anti-Explosion Mats:** (Associated Security Solutions, 2016), Anti explosion mats successfully defuse attacks using Gas and other explosives. They take the impact and reduce the pressure within the ATM, leaving your ATM even after an attack.

3. Prevention Mechanisms

Some prevention mechanisms are also under implementation on a pilot basis. The following are some of the widely implemented techniques.

The prevention methods suggested by “the Colorado banking commissioner” in (Denver, “COLORADO Department of Regulatory Agencies”, 2015) are:

1. **Check for Tampering:** At any ATM, check for signs of tampering or remote installations that don’t appear part of the machine (such as a small camera or wires that appear to be out of place). Look on the card reader and near the speakers. The keyboard should not have a film or cover on it or be more than one piece. There shouldn’t be any loose parts if you give a pull on something that protrudes, like the card reader. Even if these are in check, if something just doesn’t feel right about an ATM, don’t use it.
2. **Wiggle and Cover:** A good practice to get into is to wiggle your card a bit as you swipe it or push it into the reader. Skimmers reportedly have a harder time collecting the data because of the wiggle motion. You can also give a wiggle to the card reader mechanism, keypad and other parts to make sure nothing is loose. Additionally, always use a cover – your hand, your phone, a piece of paper – as you type in your PIN.
3. **Use Indoor ATMs:** High traffic areas with ATMs inside banks and grocery stores are typically safer than outdoor terminals. Also, the risks for skimming are higher on the weekends because criminals will install the skimmers on Saturdays or Sundays and then

remove them before banks open on Monday. Be aware that today's criminals are sophisticated and no ATM is completely safe.

4. **Always Report It:** Reporting suspicious activity or theft to your card issuer or bank as soon as possible is paramount to not being held liable to the amount you might lose if you fall victim to an ATM skimming attack. The sooner you report fraudulent activity the better!

Other than the above mentioned prevention ideas, so many mechanisms are being implemented by the ATM security firms that are as follows:

According to (Brian Krebs, "KrebsOnSecurity", 2014) "In one country no such attacks have been reported since the introduction of ink staining technology," EAST noted. Intelligent Banknote Neutralization System (IBNS) is a prevention technology in which an ink is sprayed on the banknotes, if any malpractice of looting is sensed by the system. It is under implementation, and even made mandatory in countries such as Belgium, Sweden, France, etc. These banknotes are then removed from the circulation among the public. It has one major disadvantage, that once the banknotes are inked, it cannot be used thereafter even by the central bank itself (Dominic Hirsch, 2012).

ATM security system also includes detecting sensors, video surveillance, online ATM monitoring with a battery backed-up network and alarms nevertheless the robbers are well-versed in deactivating or demolishing all security gadgets and easily snatch the cash. Even though, all these protection and detection techniques try to give security for the cash in ATM, in most cases, it fails to capture the robber.

As per the idea suggested in the patent (Staines.B, 2012) (Kenneth J Braddick, 1999), a motherboard can be fixed beneath the ATM. When any mal-functioning is detected, a safety measure is provided that invokes the computerized devices such as CCTV, alarm, tear gas cylinder and the

shutter. A slight modification can be done in the method suggested in (Kenneth J Braddick, 1999).

SOLUTIONS AND RECOMMENDATIONS

In the proposed system, all the preliminary security measures to threaten the robbers has been implemented. In addition to that, rather than using tear gas, smoke will be released from the pack kept inside the ATM, at a minimum level to make the robbers to go unconscious state. At the same time our microprocessors will send a signal to the door control unit to lock the ATM, in a rapid way. In parallel, it will send a SOS message to the nearby police station and to nearby bank branches.

The proposed system, will allow the robbers to penetrate the machine in their own way, with no disturbances to their work. Its main aim is not only to safeguard the cash, but also to capture the robbers. Here, the main aim of the robber is to steal the cash holder, the anchor design is slightly modified, such that an underground cell has been setup, beneath the cash tray of the ATM. The cash-tray is therefore, going to safe-guard by itself in an underground cell, when the robber tries to grab it.

An ATM, in proposed model includes:

1. A cylinder filled with smoke.
2. A computerized shutter is designed to shut the ATM room in rapid way.
3. A Pulley is used to hold the cash dispenser.
4. An underground cell from where the pulley is mounted that will safeguard the cash.

When a cash holder is ejected in an unusual method, the above mentioned systems will get activated.

If the robber uses any hard devices to open the ATM in a harsh manner, the system will perform the following:

1. It activates the cylinder pack to release the smoke.

Figure 1. ATM – back view

2. At the same moment, the shutter will be closed in a rapid speed. The leakage of smoke suppresses the Oxygen flow in the ATM room that makes the robber to go unconscious.
3. The metal frame fixed on the floor is opened to pull the currency box. Thus the cash tray will be safe-guarded in underground cell.

Architecture

The proposed system consists of:

1. ATM
2. Basic Security gadgets infrastructures and Sensor boards
3. Smoke filled Cylinder
4. Pulley
5. Rolling shutter
6. GPS

Figure 2. ATM room – side view

1. **ATM:** This machine is placed inside the normal room where the bankers or third party security agents fill the amount in cash trays (B1), inside cash dispenser (B) for public use.
2. **Security Gadgets:** Cameras, CCTVs, Sensors for alarm, etc., are the preliminary security gadgets that are kept ready for use. In addition, the sensor detectors like Vibration detector and Smoke detector (A) will be placed inside the ATM, which detects a harsh attack, if happens.
3. **Cylinder:** A sensor exclusively assigned for the purpose of sending signals to the cylinder pack (D) that releases the smoke (H) when the ATM has been broken in a harsh manner.
4. **Pulley:** A pulley (F) is placed beneath the ground, and it holds the cash dispenser (B).
5. **Shutter:** A computerized shutter (S) is used, which in emergency period, is activated by the microcontroller, to shutdown the ATM room, in a rapid manner.
6. **GPS:** It is used to give an alert message to the nearby police station and bank branches.

Figure 3. ATM – back view (when a harsh attack is detected)

To monitor the status of all the above sensors a Central Unit (E) will be kept. The sensing devices are connected to the Central Unit through wires, channeled via walls. As per the idea provided by (Amit Tyagi, “ProTecht”, 2016), the monitoring system will send a signal to the Central Monitoring Station at the time of emergency.

Mechanism

An ATM with preliminary security measures and sensor boards is placed in a room. The Height of cash dispenser inside the ATM is calculated (C). Below the ground level, an underground cell is provided with a height of (C+C1), where C1, is any constant. A pulley (F) is set which holds the

Figure 4. ATM Room– side view (when a harsh attack is detected)

cash dispenser (B). A cylinder (D) containing smoke is placed inside the ATM. In addition, a micro-controller (E) will monitor and activate all these appliances during hard time.

For instance, if the robbers try to break the ATM with any tools or explosives, immediately the sensor board (A) which is kept inside the ATM triggers the pulley to pull down the mounted cash dispenser rapidly beneath the ground.

At the same time, according to (Staines.B, 2012) (Kenneth J Braddick, 1999) suggestions, the cylinder (D) gets alert to release the smoke so as to make the thieves go unconscious.

Simultaneously, as per the technique suggested in (Kenneth J Braddick, 1999), a signal has been passed to the shutter and it also closes in a fraction of a second, thereby our system locks the thieves and sends alert messages to the (Kenneth J Braddick, 1999) nearby police station or bank branches.

FUTURE RESEARCH DIRECTIONS

Maintaining a huge number of ATMs by implementing the discussed mechanisms leads to the maximum security for it. On the other hand, burglars used to find all sort of techniques to by-pass it. In near future, to get full control over the burglars, technology drives the human to go cashless and card less system.

CONCLUSION

The proposed system is helpful not only to prevent the robbery but also to divert the culprits for the time duration, until the security guards reach the place. So that the thieves can be identified and the criminal rate can be possibly reduced.

KEY TERMS AND DEFINITIONS

ATM: Automated Teller Machine is a kiosk which has been filled with cash of various denominations, where a person can withdraw money at any time, by using a plastic card.

CVV: “Card verification value” on the credit card or debit card is a 3 digit number on VISA, MasterCard and Discover branded credit and debit cards.

European ATM Security Team (EAST): A ‘non-profit’ organization whose members are committed to gathering information form and disseminating EAST outputs to, ATM deployers and networks within their countries/regions.

GPS: The Global Positioning System is a space-based navigation system that provides location and time information in all weather conditions, anywhere on or near the Earth where there is an unobstructed line of sight to four or more GPS satellites.

Intelligent Banknote Neutralization System (IBNS): IBNS is a prevention technology in which an ink is sprayed on the banknotes, if any malpractice of looting is sensed by the system.

National Cash Register: NCR is an American computer hardware, software and electronics company that makes self-service kiosks, point-of-sales terminals, ATMs, Check processing systems, barcode scanners, and business consumables.

Physical Attack: To launch a physical assault (against) with or without weapons.

Sensors: A device which detects or measures a physical property and records indicates or otherwise responds to it.

Artificial Ethics

Laura L. Pană

Polytechnic University of Bucharest, Romania

INTRODUCTION

The possibility to conceive and to effectively apply a new ethics, deeply explicit and valid in theory, strongly relevant in practice, and suitable for both artificial and human intelligent agents is argued in this chapter.

The whole intellectual history shows that long ago humans were aware of their specific gift to add artificial objects of social (material or ideal) kind to those natural, i.e. to create culture, as an extension of nature. The oldest cyberneticist, Plato, in his *Republic*, offered the first description of society as a human design and an artificial product. Aristotle, in his turn, wrote in *Politics* (II. 5) about the automatic tools and installations of Daedal and even about the mentally controlled tripods created by Hephaestus, which served the “band” of gods.

For the specific field of moral culture, P. Danielson outlined the artificiality of morals and analyzed the possible degrees of creativity by which moral values are invented and moral culture is renewed (Danielson, 1998). He explicitly writes: “important parts of morality are artificial cognitive and social devices” (p.292). Even before, J. Bentham, who explored both the human mind and the *Table of Springs of Action* (1812), understood the artificial character of morality and described “the whole fabric of morals”. He elaborated a both comprehensive and operational moral theory, and coined a specific calculus, based on the central moral value of his vision.

This study identifies theoretical possibilities to model moral conduct, and aims to find and to develop a set of moral prerequisites (mental aptitudes and practical skills), available and suit-

able for any kind of moral agents. In this way, the axiological foundation of the new ethics may be continued by an attempt to identify an appropriate and operable value-set, selected from a complete ethical system.

The main practical contributions covered by chapter: indicates a well-founded way to effectively connect moral theory and moral practice; proposes a complex but feasible strategy of designing artificial moral agents, detailed in a few operational phases; makes a concrete proposal of modeling and implementing moral action in the behavior of artificial agents; shows the new possibilities offered by the present changes in value systems for effective moral agents designing and training.

BACKGROUND: SCIENTIFIC, TECHNICAL, AND PHILOSOPHICAL PREMISES OF ARTIFICIAL ETHICS

Some theoretical deficiencies of great ethical systems and some practical difficulties of applying abstract moral values in concrete conditions by individual agents have been frequently discussed by ethicists, in their common effort to establish a new foundational theory of moral choice, moral freedom and then of a deep moral conduct.

The nature of artificial agents able to behave ethically has been extensively studied. This study led to different conclusions, which can however be considered convergent. Among other features of moral agents McDermott emphasizes the capacity to take specific, moral decisions, just like (Moor, 2005 and 2011), and analyses ethical reasoning, seen as the main decisional sub-structure (McDermott, 2011). The role of free will is also

detailed by him, while the will itself is refined up to temptation. J. Gips also emphasizes the role of free will, as of conscious choice (Gips, 2011), and shows the necessity to develop perceptual and non-symbolic aspects of morality, and to favor training, not teaching of abstract theories. (p. 250). Wallach and Allen correlated autonomy and sensitivity (to moral considerations) as defining dimensions for artificial moral agents (Wallach & Allen, 2009). For J. P. Sullins, the relevant aspects of moral agency are autonomy, intentionality and responsibility (Sullins, 2006). L. Floridi studies the distribution of the necessary factors for an ethical behavior - interactivity, autonomy and adaptability -, between a large category of agents, such as natural objects, ecosystems, technical systems, organizations and humans. Intentionality is also associated, as the most important, responsibility, which is here distinguished from accountability (Floridi, 2011, p. 205). The list of the required capacities is also extended in (Anderson, 2011) by sentience, self-consciousness, reasoning, and emotionality. Moral agency is also considered here, although some of the above indicated elements are integrated into the very internal structure of action, as aspects or parts of interests, motivations, decisions and goals. Other authors dedicated to define agency include, among other features, normativity and asymmetry (Barandiaran, Paolo, & Rohde, 2009). Spatio-temporality, also assigned to agents by them, actually is a universal property. Moral agent's study, as part of the artificial intelligent agent's theory, may be illustrated including by (Pană, 2005c), a study on artificial cognitive agents, followed by (Pană, 2008b), on cognitive and moral agents, viewed in their evolution (Pană, 2006b). This chapter continues and deepens the growing list of the possible features previously assigned to artificial moral agents by (Pană, 2006a; Pană, 2012), especially by attributes related to consciousness and value systems.

Many scholars believe consciousness is a condition of moral judgment and moral conduct. Here the approaches range goes from those philosophical, neurobiological and psycho-sociological up

to computational ones, such as those which mark the progress in the field from diverse perspectives (Gamez, 2008), which ambition to build a conscious machine (Angel, 1989) or which explore large areas of the field but also thoroughly study a series of essential topics (Holland, 2003). A study on axioms and tests for the presence of minimal consciousness in agents establishes as eligibility criteria perception, imagination, attention, planning capacity and emotion (Alexander & Dunmall, 2003), in conformity with their set of axioms (p. 9-10), which is adequate for the consciousness understood, *apud* Dennett, as "a virtual machine running on a parallel neural computer" (p.8). The contribution of the present chapter in this matter is based on studies concerning an integrative model of brain, mind, cognition and consciousness (Pană, 2008a), as well as on a few forms of social consciousness (Pană, 2000), and consists of an analysis of the internal structure of moral conscience, in order to find which of its components and levels are suitable to be modeled and implemented in artificial moral agent programs.

The project of building an artificial ethics, suitable both for human and artificial moral agents, have to include, from the start, a value-centered approach and vision. In the today dedicated literature, the values under discussion are those human, and mainly those already recognized in the moral field, such as good and evil, right and wrong, but also a few others, implied both in current human activities, as in the human-computer interaction, e.g. egoism and altruism, treated in (Floridi, 2011), together with values occurring in organization environments, such as equal opportunity, financial stability, good working and holiday conditions for employees, good service and value to their customers or shareholders, and honesty, integrity and reliability to other companies (p. 205). Inspired by competing and cooperation needing contexts, other authors study the relationship between altruism and reciprocity, as in (Danielson, 2002), where he develops evolutionary agent-based models in order to test their conjecture in various cases. Responsibility, which remains a core value

in the new, computer-centered and wired work and life environment, is also frequently studied, sometimes with outstanding results (see Noorman, 2014), linked or not with its pair in the accredited ethical binomial. The possibility to conceive and to effectively design value, motivation and norm directed artificial and human intelligent agents was anticipated in works on the evolution from Virtue Ethics to Virtual Ethics (Pană, 2005a), by studies dealing with crucial events in IST development (Pană, 2010), which could be concluded with value computing and motivation inventing (Pană, 2006c), and by others that aim to model the evolution of value systems (Pană, 2004b), as through essays to discover or to design common skills of artificial and human moral agents which enable them to pursue specific values, such as in (Pană, 2006b).

MAIN FOCUS OF THE ARTICLE: TO GENERATE AND APPLY AN ETHICS VALID IN THEORY AND EFFECTIVE IN PRACTICE

The current attempts of moral values, principles and norms implementing raise difficult problems in the case of both human and artificial agents. Moreover, some parts or even levels of a complete moral system are weak or are even missing from the “roadmap” of the common man. Moral reflection, especially, which is conditioned by the construction and assimilation of a scientific and philosophical superstructure of moral life, is habitually in this situation.

A project of technical implementation of human morality as such in artificial agents is counter-efficient and therefore counter-indicated because of its internal contradictions and failures. This is one of the reasons from which the artificial ethics project includes, as an implicit goal and as an indirect result, a renewal and an optimization of the human morality itself, by a complex, interdisciplinary endeavor. Some additional difficulties appear, mainly from an operational perspective:

- How can moral values be put into practice by intelligent machines which use just an abstract form of intelligence?
- Moral values are synthetic values (Pană, 2008b) which require a particular type of knowledge - practical knowledge;
- A special kind of knowledge is also necessary for their understanding – evaluative knowledge - see (Pană, 2000);
- The general, vague and often counter-intuitive features of values call for creative intelligence;
- Their practice may require several mental (individual) aptitudes and cultural (social) attitudes;
- Can “natural evolution” of programs be adapted for a moral dimension of machine’s action? Singularity, un-repeatability and irreversibility of moral decisions are other characteristics of moral action that should be further considered.

To add a moral component in a machine architecture and to generate thus a “moral life” of artificial intelligent agents is a hard and time requiring task, but its accomplishment is helped by the nature itself of the moral phenomenon, that has several favoring features, such as:

1. The multitude of the implied capabilities, skills and competences and, by consequence, an increased number of ways to achieve the goal;
2. The synthetic nature of many of these factors, such as moral intelligence, whose study was initiated in (Pană, 2005c), continued in (Pană, 2006a; Pană, 2008b) and will be deepened in a study now in progress;
3. The fact that moral values are active, are observed or are even generated in each activity field, which also offer their specific means for their accomplishment;
4. Moral conduct transcends biotical and psychical conduct, and as a social conduct it is or will be at the reach of both human and artificial moral agents;

5. The spiritual nature of moral values, that make them able to be formalized and then accessed by any kind of agents;
6. If developed also as cultural beings, by training or even by educational activities similar to children's cultural formation, artificial agents will be able to effectively deal with specific cultural values;
7. The desirable and possible cooperation of entities;
8. The highly normative structure of moral conduct;
9. The possibility to develop moral techniques as variants of intellectual techniques;
10. The chance to apply a wide range of methods (philosophical, psychological, technical);
11. The opportunity to conceive and to design all practical intelligence forms as grounded on values, motivated by projects, oriented by goals, and realized by techniques (intellectual or instrumental).

SOLUTIONS AND RECOMMENDATIONS: ARTIFICIAL AGENTS WITH QUASI-COMPLETE ETHICAL SYSTEM

A Way to Design Artificial Moral Agents, Directed by Values and Norms

A promising solution may consist of the following, complex but feasible strategy, which includes as phases:

1. A both structural and functional analysis of a complete moral system, corroborated with
2. A critical, and in the same time constructive inquiry of the now operating technical achievements in the general theory of artificial intelligent agents;
3. Modeling each component of ethical conduct as a cluster of activities, composed of

actions, acts and actema. Mental activities will be decomposed in functional blocks, processes and operations.

4. Using an adapted cybernetic chain of action, with the following necessary steps of moral action: cognition → intention → motivation → decision → execution → evaluation → anticipation.

Overall, the strategy is to enrich, as much as possible, the usual software architecture of artificial agents, by adding to the cognitive and other habitual architecture components, an intentional architecture, then a motivational one, a decisional and an operative architecture, an evaluative and, finally, a projective architecture. The prospective logic used in (Pereira & Saptawijaya, 2011) can here be helpful. A coordination and control center of the general software architecture becomes necessary in an action area as complex as the ethical one.

In modeling and implementing moral action in the behavior of moral agents, the cybernetic circle has to be not only complex, but also complete. It will include, besides the well-known *feedback*, also the *feed-before* and even the *feed-up* connections. In this way, it will be transformed into an open ellipse, and in perspective, in an upward elliptic helix, that can represent including ethical aspirations. Openness here means forward, not only backward looking and acting, and new projects initiating.

For the first phase of the proposed strategy the following steps seem to be suitable and now feasible: 1 - to describe the internal structure of a complete ethical system; 2 - to study its components to find out if they can be applied by artificial agents, once translated into explicit and clear instructions, and 3 - to test the behavior of moral agents in an environment that models as accurately as possible the features of moral practice.

The Internal Structure of a Complete Ethical System

The overall picture of the moral system, specifying the place and the internal structure of ethics, as one of its sub-systems is as follows:

1. Moral practice;
2. Moral conscience:
 - a. Moral skills or habits, acquired by living in a moral community;
 - b. Moral affectivity, initially manifested as moral emotion, later on possibly developed into moral feelings;
 - c. Specific norm-based moral judgment and moral decision, facilitated by personal intelligence or even by specific education;
 - d. Moral beliefs or convictions, that are complex, both rational and affective formations and, at the top of the internal structure of moral conscience,
 - e. Moral reflection.
3. Ethics, which is the elaborated, theoretical, meta-theoretical and methodological level of a moral system, has itself a systemic feature, and presents the following internal structure:
 - a. Moral values;
 - b. Moral principles;
 - c. Moral norms, rules and procedures;
 - d. Ethical models, which are the result of various, theoretical, methodical and integrative attempts to establish a functional, harmonious and durable connection between the first three levels of the ethical subsystem (3), and the practical moral conduct (1), thanks to the mediation of (2), the moral consciousness subsystem.

In the framework of traditional morality, moral problems are emerging still from the first, habitual level of the morality, because at this level, moral norms are introduced through the system of posi-

tive and negative sanctions, which generates the corresponding, sometimes positive, but mostly negative reactions, at the second, affective level of moral life.

This is the first cause that makes humans live their moral life not as a form of freedom, but as an experience of coercion. The second one consists of troubles induced by incongruity between abstract ethical values and concrete conditions of their application in moral conduct. The aggregate effect of these causes leads to the dubitative, inconsequent or even contradictory nature of moral attitude and constitutes a major and durable inconvenience of traditional morality.

Moral decision seems to be the touchstone of coherence in a moral system, because it is the main activity able to ensure the continuity between the system of accredited values, principles and norms organized in various models, respectively the current morality. The task to bridge the gap between moral theory and moral practice may be accomplished by starting from a deep analysis of the present state and trends of the moral value-system.

Current, Favoring Changes in the Ethical Value System

As favoring axiological processes for the accomplishment of a new ethics, the following ones can be summarized:

- The homogenization process of different action types, due to their increasing scientific and technical content and features, also generates the phenomenon of incorporating into a single and almost neutral category – that of error -, all the wrong or failed results of different human enterprises, named before bad, wrong, guilt or sin, which become, in this way, its derivatives;
- The tendency of passing to a more permissive or even relativistic evaluation way, which no more considers as irreparable and

then punishment needing, all the wrong or failed results of human enterprises, but as repairable or even reversible, and which allows a more nuanced situation analysis and decision;

- The tendency of polarization in the hierarchy of values, by which the groups of highly, respectively weakly appreciated values tend to move toward extremes, while a third group, that of basic values, becomes thus central, i.e. strongly felt and widely shared;
- The complementary tendency, that of concentration of human needs, by which some needs, often basic needs, even disband several of the old values;
- Some needs, spectacularly increasing until recently, regress now in some respects, e.g. the cognitive need, which degenerates into the need for information and data;
- Knowledge as a value recovers more than what loses in favor of information, through enhanced applicability, through successful combinations of philosophical, scientific, technical and moral cognition;
- The emergence of hybrid approaches to technical and moral issues, as evaluative cognition and prospective cognition (Pană, 1988) or cognitive emotion (Wallach & Allen, p.155), operationally treated by them as “cognitive representation of emotions” (p. 152) also enriches this axiological space;
- Information however becomes the central value of the whole value system and,
- The informational language is now the only one shared with our cybernetic creations;
- The new outcomes in programming decision sequences, action structures and behavior models in artificial agents, which may be seen as steps in creating conditions for appropriate ethical values applying in this field.

The convergent effect of all these changes in the present value system is the generation of new possibilities to develop moral calculation, moral agents, and a moral interaction of human and artificial agents.

An Appropriate Central Value for the Field of Artificial Ethics

The *good* and the *bad*, which were seen, for now, as central in ethics, are not even specific to the moral realm, as demonstrated in (Pană, 2000, pp. 70-86; 108), because they are used in all types of activities as components of a general foundation of their own value-systems.

Therefore, *good* and *bad* are functioning rather as a pair of *meta-values*, which may guide and evaluate any kind of human conducts, almost always characterized by multiple and often contrary needs, interests and motivations.

The *good*, especially, as the most appreciated and widely used axiological construct, is general enough and indefinite too, as well as comprehensive and inspiring, to function as an efficient evaluative basis for the entire class of intentions, motivations, choices and results of human action.

But from the chosen perspective and for the stated purposes, good and goodness, together with their associated virtues, are not useful in the case of beings (for now) without consciousness, such as some intelligent, trainable or even learned, robotic (physical or virtual) agents.

Correctness could be such a value, at the same time strong and universal, but however within our reach, thanks to our recently acquired scientific and technical skills, and because (of):

1. It is suitable both for human and artificial morality;
2. Its increased clarity, intelligibility and applicability;
3. It may function with the same efficacy
 - a. In all types of activity, and
 - b. At every level of human or artificial conduct.

But can the evoked conditions and difficulties of moral action be eliminated by the simple correctness and can be this moral aspiration as strong as goodness was in the history of morality? As a spiritual realm of being, morality was lead, at least until now, by values which cumulated methodic and ergonomic, but also motivational and projective functions.

FUTURE RESEARCH DIRECTIONS

The presented findings may be continued by following a set of research and activity directions, dedicated:

1. To set-up a unitary and interdisciplinary strategy in artificial moral agents designing, a strategy which could be philosophically grounded, scientifically supported and technically realized.
2. To model moral conduct as a net of cybernetic connections, governed by the complete set of cybernetic interaction types - feedback, feed-before and feed-up -, able to ensure inclusively the development (ascending evolution) of a population of human and artificial agents.
3. To describe and to decompose each cybernetic step of action (cognition, intention, motivation, decision, execution, evaluation, anticipation) in practical units: activities, acts and actema.
4. To use and invent new information and knowledge-based soft techniques and technologies, appropriate for intelligent automatic social systems instantiating and mastering.
5. Building, modeling and implementing new sets of moral, scientific, technical, economic and political values with the aim to restore the social life on cultural bases.

CONCLUSION

By proposing a new ethical approach of IST issues and AI projects, and by opening a new interdisciplinary research field – that of Artificial Ethics -, we hope to a) eliminate the internal contradictions which were born wherewith some ethical theories; b) surpass the practical failures of human moral conduct; c) allow an axiological foundation of new moral codes, adequate for various types of intelligent systems; d) ensure a conflict-free and effective human-machine cooperation and e) stimulate the common evolution of human and artificial intelligent agents. The study distinguishes the appropriate values for the contemporary ethical environment and proposes a comprehensive and operational strategy of their implementation. Artificial Ethics building will be, in fact, a product of the co-cognition and co-construction of human and artificial intelligent agents in their intertwined evolution on the background of different but concurrent processes of nowadays, such as the rising of a multiple artificial intelligence or maybe of a general artificial intelligence, as of artificial cognition and artificial discovery, artificial activity and artificial society. Artificial ethics will be generally applicable and, because it will reduce or eliminate many difficulties of biotic, psychic, social or historical and even cultural sort, it will treat mainly issues related to distinct fields of activity, types of tasks and degrees of complexity. Thus, artificial ethics will expectedly be the first effective ethics.

KEY TERMS AND DEFINITIONS

Artificial: Any completely new social outcome of human activity, either theoretical or practical, such as a concept, a method or artifact, a social

body, a system of relations or an institution, therefore, any kind of real mental construction or material achievement.

Artificial Ethics: Is the present stage of the evolution from Philosophical Ethics to Scientific Ethics and to Technoethics. It is also based on important findings made in computer-centered ethical fields such as Information Ethics, Computing Ethics, Machine Ethics and Web Ethics. Artificial Ethics is both a conceptual and technical research field and a theoretical and practical area of moral action.

Artificial Moral Agents: A sub-set of artificial intelligent agents, which have classes of attributes of artificial agents, and other ten specific features, gradually identified in (Pană, 2005c; Pană, 2006a; Pană, 2006b; Pană, 2008b).

Axiology: A fundamental constitutive field of philosophy, which studies the genesis, structure and functions of values, their cognition and realization, as well as the dynamics of value systems. It is also developed as a science, practiced with various instruments, including those logical, as in Formal Axiology.

Co-Evolution (of Human and Artificial Moral Agents): The process and the product of the co-cognition, co-sentience, co-operation and co-construction of human and artificial intelligent agents, by which they develop new and common functions, skills and characteristics, which become sources of their further evolution.

Complete Cybernetic Connection: Is a cluster of different types of connections, which consists not only of the well-known *feedback*, but also of *feed-before* and even of *feed-up* connections, all of them necessary in modeling and implementing moral action in the behavior of artificial moral agents.

Value Systems: Besides its geosphere, biosphere, sociosphere, technosphere, infosphere and noosphere, our world also presents an axiosphere, which may be analyzed inclusively in terms of Systemics: each subsystem of a social system has its own value-system, with a central value, around which orbit specific values. Similarly, every epoch imposes its own core value which attracts the appropriate set of values.

Artificial Intelligence

Steven Walczak

University of South Florida, USA

INTRODUCTION

The ENIAC computer unveiled in February 1946 is considered by many to be the first programmable digital computer. Soon after this first computer was initialized, human researchers started to dream of intelligent machines. Alan Turing (1950) proposed a means for computers to demonstrate intelligence. Thus, the science of artificial intelligence (AI) was created. The term *artificial intelligence* was first coined in August, 1955 (McCarthy et al., 2006). The goal of AI is to create computer programs, possibly embedded in sophisticated hardware such as robots, which are capable of intelligent thought, ultimately creating new knowledge. Intelligent systems should be able to perform any task normally associated with human cognition and intelligence, such as goal setting, goal seeking, path planning, and problem solving.

There are two schools of thought within AI. The first seeks to create machine intelligence by

emulating the way humans think. An example of this approach is the MYCIN expert system, which utilized the problem solving processes of human experts in order to diagnose bacteriological infections (Shortliffe et al., 1975). The second is interested in creating intelligence through whatever mechanisms are available, regardless of its similarity to human thought processes. An example of this second approach is the Deep Thought (renamed Deep Blue® after IBM® purchased the program from Carnegie Mellon) chess playing program which utilized massively parallel computer architecture to achieve chess playing expertise by being able to examine game trees to a much deeper depth (Newborn & Kopec, 1989).

The Turing test (Turing, 1950), depicted in Figure 1, essentially states that if the output of an AI program cannot be distinguished by a knowledgeable human being who cannot see the respondents from responses made by another human, then the machine is intelligent. The Turing test has been

Figure 1. Turing test; judge in main room tries to determine which room has the computer AI and which room has the human by asking questions and evaluating Room A and Room B responses

DOI: 10.4018/978-1-5225-2255-3.ch009

criticized that it doesn't really evaluate intelligence, just a computer's ability to imitate human conversational responses to questions. The Eliza program is an early version of what has become known as a chatbot (Weizenbaum, 1966). Eliza conversationally performed psychotherapy, but in actuality was simply using canned responses to pre-identified keywords present in the human user's responses to Eliza's statements and questions. A modern version of the Turing test is the annual Loebner Prize competition (AISB, 2016).

An interesting outcome of the Turing test is the identification that certain abilities humans may take for granted, such as speech, vision, and hearing are extremely complex for computers to perform, while complex mathematical operations are extremely easy for computers to perform. Additionally, Turing's ideal is for AI-based computers to have global knowledge, similar to humans, so that they could converse on a wide variety of topics intelligently. However, as shown by the Eliza project, early AI research was focused on solving much more narrowly defined problems within single domains. This trend of having highly specialized intelligence to outperform human experts in problem solving within a specific domain or for a specific problem with a domain is still continued today.

The field of AI has numerous disciplines:

- **Agents, Also Known as Intelligent Agents, Mobile Intelligent Agents, or Mobile Agents:** The use of atomic processing entities that collaboratively work to solve problems.
- **Artificial Life:** Systems that model natural life processes, behaviors, and evolution, both for investigating biologic and population dynamics and to be used in problems solving.
- **Artificial Neural Networks, Also Known as Neural Networks and Connectionist Systems:** Machine learning systems based on the processing of the human brain.
- **Cognitive Modeling:** Creates models of cognitive processes to explore the nature of thinking and problem solving.
- **Computer Vision:** Creating the ability to accurately interpret visual data such as pictures, animations, and movies.
- **Expert Systems, Also Known as Knowledge Based Systems:** Computer programs that simulate or surpass human expertise with a defined domain or collection of domains.
- **Evolutionary Computation:** Genetic algorithms or genetic processing.
- **Knowledge Acquisition:** Capturing human knowledge normally at an expert level.
- **Knowledge Representation:** Encapsulating acquired knowledge in a machine usable format.
- **Machine Learning:** Designing processes that enable machine intelligence to grow beyond the bounds that have been statically programmed into the AI application.
- **Natural Language Processing, Also Known as Speech Processing:** Systems that can understand and produce both written and spoken language.
- **Planning:** Development of intelligent plans for accomplishing goals, including game playing systems.
- **Robotics:** Development of automated hardware systems that can perform human-like tasks, including robots that mimic animal or human form and behavior.

The many disciplines of AI are not necessarily independent, but frequently interact with each other to try and create more comprehensive intelligence in computers. For example, a human like robot would utilize research from cognitive modeling, computer vision, knowledge acquisition, knowledge representation, machine learning, natural language processing, and planning in addition to the obvious robotics discipline. New subdisciplines are often created when an existing

disciplines begins to grow, such as artificial neural networks and evolutionary computation being outgrowths of the original machine learning discipline and knowledge acquisition and knowledge representation having started in expert systems research. With the many and often interacting disciplines within AI, the field of AI research serves as a complex milieu of tools for mimicking or surpassing human intelligence or creating machine intelligence to solve a vast collection of research problems.

HISTORICAL BACKGROUND

Early work in AI revolved around basic problem solving, including development of intelligent search strategies, development of heuristic methods for reducing problem complexity, and goal seeking and planning behaviors (Pearl, 1984). Although AI research had been progressing since its inception in the 1950's, AI fever hit in the mid-1970's with the demonstration of the MYCIN expert system, which was able to outperform individual physicians on diagnosing specific types of bacteriological infection. Similar to the Gartner hype cycle (Linden & Fenn, 2003), once practical applications of AI theory were established (e.g., MYCIN), research and expectations from AI grew rapidly, but often outpaced reality. Large government grant projects in the 1980's to foster AI research and AI application development often fell short, due to an overestimated potential for AI at the time. Knowledge based and intelligent systems fell out of vogue and funding contracted significantly, but academia kept AI research alive. Research shifted from expert or knowledge-based systems to more machine learning oriented systems, including artificial neural networks and genetic algorithms. Nowadays research in AI is once again increasing and this may be due in part to the success of AI research that was evaluated using games (e.g., backgammon or chess) and the entertainment value of such AI games, which caught the public's attention.

Games have often formed a foundation for initial and exploratory research in AI, especially in checkers, chess, poker, and other strategy games. The Deep Blue chess playing program of IBM played and lost its original 6 game match in 1996 under tournament conditions to then world champion and chess grandmaster Gary Kasparov, but did manage to win one game and with tied games lost to Kasparov with a match score of 2 to 4 (Newborn, 2012). A rematch occurred the following year and Deep Blue was able to win two games outright and the 6 game match against Kasparov with a match score of 3½ to 2½ (Newborn, 2012). Now that chess had been conquered, AI research evolved to investigate more difficult game tress, such as Go and shogi (Japanese chess-like game played on a 14 by 14 board with 8 different pieces and 10 movement patterns). Recently, Google's AlphaGo program, which originally defeated Fan Hui, a professional Go player, without any handicap in 2015, defeated in 2016 Lee Sedol, a world champion Go player, in a 5 game match (Wang et al., 2016).

Expert systems and intelligent game playing programs traditionally operate within a well-defined and narrow domain. The GPS (General Problem Solving) program is one of the early instances of combining a separate reasoning mechanism with domain knowledge to perform general purpose problem solving (Newell, Shaw, & Simon, 1959). The GPS program is able to prove logic and predicate calculus problems and can solve brain teasers such as the Towers of Hanoi problem (see Figure 2), but did not advance beyond this due to the intractable nature of searching the growing decision trees. The Cyc project is an early attempt to create an ontology for common sense reasoning (Lenat & Guha, 1989). The lack of common sense or "deep" knowledge in many AI systems is cited as a significant shortcoming (Carter, 2007). Cycorp, the company that owns and researches advances to Cyc, has made their Cyc database available through their OpenCyc project.

Games are used in AI research as a well-defined and understood testbed for defining new learn-

Figure 2. Towers of Hanoi problem (showing 5 disks): move disks one at a time from Peg A to Peg C and a disk may never be placed on a smaller disk (the original problem had 64 disks)

ing, search, and other AI techniques. Once these AI-based methods are proven in a game domain, the goal then becomes to generalize these newly proven AI methods to new problem types, generalizing the solution methodology, such as cognitive modelers in adversarial game domains generalized to simulators (Walczak, 2003).

Although not a game playing program, IBM's Watson system has also caught public attention when it defeated Ken Jennings (longest winning record of 74 games) and Brad Rutter (highest payout of \$3.25 million) in the quiz show Jeopardy (Best, 2013). The Watson program at IBM is similar to Cyc in that it is a system to perform common sense reasoning using very large data ontologies. The Watson system combines cognitive modeling, data mining (knowledge acquisition), knowledge representation, machine learning, and natural language processing, to be able to answer questions intelligently over a wide variety of topics. Specialized versions of Watson are under development for business oriented systems and medicine (Ferrucci et al., 2013).

The successes of AI may be appreciated in that many of the accomplishments of AI are frequently no longer recognized as AI, but rather as "the way things are". As an example, data mining algorithms for processing big data were originally developed back in the 1980's by AI and other re-

search disciplines (Chen, Chiang, & Storey, 2012). Other more common examples are the decades of natural language processing research (starting with Chomsky's (1957) formal grammar) that resulted in commonly used products such as Dragon's Naturally Speaking program and Apple's Siri and also mobile agent research that has led to today's search engines such as Google's search engine.

WHERE TO NOW?

AI research has been progressing steadily for the past 65 years. Much of AI research still focuses on solving specific problems within narrow domains and discovering heuristics for more efficient problem solving within specific domains. New problems arise continually and AI techniques provide reliable methods for developing reasonable and reliable solutions to these problems. Examples of ongoing problems are accurately predicting stock and commodities future movements, accurately diagnosing different types of cancers or other diseases, and creating self-sufficient autonomous vehicles or robots capable of intelligently reacting to unforeseen situations. Thus, the focus on AI based solutions to problems within narrowly defined domains will continue to be an ongoing research emphasis within AI, particularly in fields

that operate under uncertain information or conditions such as medical decision support systems (Miller & Geissbuhler, 2007).

Developing more global knowledge and intelligence may result from efforts to combine AI techniques and also to embed multiple AI-based systems within a single product to increase the scope of intelligence brought to solve more generalized domains and their problems. This approach is being used in medicine by embedding AI-based solutions to very narrow and specific problems into a utilized tool like an electronic medical record, to assist physicians and other healthcare providers in decision making across a much wider range of problem types (e.g., diagnosis and treatment plans across a wide variety of illness types).

The goal of creating a machine that rivals or surpasses the intelligence and reasoning capabilities of humans is still an ongoing goal of AI. The two problems currently being tackled by AI researchers in this respect are the encapsulation and usage of common sense knowledge and creating deep knowledge or understanding of the problem and corresponding solution. The first indicates that simply having knowledge about a specific domain such as the properties of metals and materials for a bridge building AI is insufficient to solve many problems that will be faced by the system that must rely on common sense knowledge available to humans, such as the heat and lack of humidity in desert regions, or the near constant precipitation in other geographic locations. Combining common sense reasoning with domain specific knowledge is a significant problem and is related to the knowledge acquisition and representation of common sense knowledge as well as inferential learning mechanisms to know when a specific piece of common sense knowledge should be applied as part of the problem solving process.

The second goal of creating understanding, sometimes referred to as “deep knowledge,” moves AI towards truly being intelligent. Current AI systems perform very well within their speci-

fied domains by using large knowledge bases of specific domain knowledge, or ontologies in the case of Cyc and Watson. While these AI are very efficient pattern recognition machines and able to apply induction, deduction, analogy, and other types of learning mechanisms to discover answers to difficult problems, they do not understand the reason why a problem may be important to solve and are not able to explain how the discovered solution makes sense, other than reciting the various rules or knowledge base facts used in determining the recommended solution.

ETHICS AND AI

A learning machine ultimately requires the capability to re-write its own code, which is certainly possible in many current programming languages. An ethical question arises from this goal of making machines intelligent and arises out of fears implanted in the human psyche from science fiction, such as robots finding ways to circumvent the three laws (Asimov, 1942). What happens if we succeed in creating a computer entity that can outthink its human creators and is capable of modifying its own code? Due diligence is required of AI researchers to accurately test their systems to make sure they are reliable, repeatable, and accurate. Along with these measures, as the day of a truly intelligent machine approaches, researchers will also be faced with providing mechanisms to disable a possible rogue machine.

As with researchers having a responsibility to develop accurate and reliable AI systems, it is also incumbent upon professionals to utilize the best technology available for performing their tasks, and when it comes to decision making or problem solving this implies AI-based systems. Legal precedent has already been set to establish the need of rational people to utilize the best technology available (see the Hooper decision in Berner and La Lande (2007, pp. 12-13)).

FUTURE RESEARCH DIRECTIONS

As indicated above, one of the challenges for AI research is to develop an intelligent machine that can understand and make sense of the world, similar to how children absorb and new knowledge and create understanding from that knowledge (Rutkin, 2016). Future AI research needs to continue to improve upon existing research to strengthen the current results. New AI research must focus further on not only imbedding knowledge, but developing intuition and inferential machine learning methods that will enable AI systems to acquire new knowledge about novel domains and develop reasonable understanding of these domains for appropriate problem solving behaviors.

While AI successes have been widely adopted and incorporated into what is perceived by the public as common or expected practices, education efforts need to be developed to remind the public of the AI origins of much of their current technological expectations and the need for sustained support and development of new AI research. One way to help emphasize the power of AI for solving complex problems is to incorporate humans back into the loop. Partnerships between AIs and humans will continue to advance research and improve not only human abilities, but also the capabilities of the AIs working in collaboration with humans (Rutkin, 2016).

CONCLUSION

Although the idea of thinking machines may be frightening to the general public, the AI research community has succeeded in producing solutions to many difficult problems. These solutions have reduced costs, improved time utilization, improved the quality of health, and many additional outcomes that have improved overall business and life and overcome uncertainty in complex decision making. AI systems tend to operate within narrow domains, but do so at the level of human experts and frequently surpass the problem-solving

performance of human experts. A new trend of embedding multiple AI-based systems within a current information system tool allows bringing multiple types of intelligence and expertise to bear on domain problems. The future of AI is promising as ever expanding research demonstrates solutions to more and more problems.

A

KEY TERMS AND DEFINITIONS

Artificial Neural Network: A collection of interconnected processing elements known as neurodes that mimic the electrical connectivity in the human brain to produce intelligence.

Expert System: Also known as knowledge based systems, a computer program composed of a knowledge base, often represented as if-then production rules, an inference engine, and a user interface which typically includes an explanation facility to educate users on the decision making process of the expert system.

Game Tree: A knowledge representation structure shaped like a decision tree. Nodes of the tree represent game positions possible through legal moves (from the position in the parent connecting node). The layers of the game tree expand or contract based on the possible legal moves at that point in the game. It has been estimated that the game of chess has 38^{84} possible positions in its game tree (Marsland & Campbell, 1982).

Heuristic: A rule of thumb used to reach a conclusion using only partial knowledge. While not guaranteed to be perfect, the heuristic should provide a reasonable approximation of a correct solution.

Three Laws of Robotics: Sometimes referred to as Asimov’s Laws of Robotics or simply the Three Laws are a set of science fiction principles to govern intelligent/thinking robot behavior so that no harm comes to mankind. The laws are: 1) A robot may not injure a human being or, through inaction, allow a human being to come to harm; 2) A robot must obey the orders given it by human beings except where such orders would conflict with the First Law; and 3) A robot must protect its own existence as long as such protection does not conflict with the First or Second Laws.

INTRODUCTION

The study of intelligence is one of the oldest disciplines. Artificial Intelligence (AI) is a very growing and actively changing field. In this paper, we present a profound review of the AI. After defining it, we briefly cover its history and enumerate its major fields of application. Also, the test that defines an artificially intelligent system called The Turing test, is also defined and detailed. Along the way, we describe some AI tools such as Fuzzy logic, genetic algorithms and swarm intelligence. Special attention will be given to neural networks. We also present the future research directions and ethics.

BACKGROUND

Artificial intelligence (AI) may be defined as the branch of computer science that is concerned with the automation of intelligent behavior (Luger & Stubblefield, 1993). It is a research area and a field of technology that creates both software and hardware sophisticated features in order to

include virtual artificial agents. It can be divided into two categories based on thinking and acting shown in Figure 1.

Alan Turing, a British mathematician, introduced the ‘Turing test’ for intelligence, referred to the accredited test as the imitation game (Hodges, 2002). The famous test appeared in Turing’s paper, *Computing Machinery and Intelligence*, was published in October 1950 in the philosophical journal, *Mind* (Turing, 1950). In fact, this test was designed to provide a satisfactory operational definition of intelligence (Russell & Norvig, 2009).

This Turing test states four conditions for a computer to be called an intelligent machine. The first is the natural language processing (Kok et al, 1993). The second condition concerns the knowledge representation (Russell & Norvig, 2009). The third is automated reasoning (Kok et al, 1993). The computer has to be able to reason based on the knowledge that has been put in its memory. Finally, the machine must be able to learn from its environment (Kok et al, 1993). Some scientists have argued that the Turing test presents some limits such as not rating the intelligence of the machine (French, 1990).

The apparition of artificial intelligence was due to the inventions in electronics and other disciplines (Buchanan, 2005). The term was first coined by John McCarthy in 1956 in the conference: Artificial Intelligence, a new term to the human understanding (Stewart, 2000). The fifties saw the growth of an AI community and witnessed the opening Dartmouth Artificial Intelligence Conference and the creation of DARPA: Defense Advanced Research Projects Agency (Knight, 2006). This conference (McCarthy et al. 2006) made it possible to examine the use of computers in order to process symbols. Doubts amongst some researchers concerning the efficiency of machines began to occur in the 1960s (Coppin, 2004). In the 1970s, the AI industry went through a short era described as AI Winter where AI faced a dramatic regression (University of Washington, 2006) due to factors such as the failure of machine translation in 1966. The expert system is a computer system that imitates the decision-making ability of a human expert, was first created in the 1970s and then spread in the 1980s (Peter, 1998; Leondes, 2002). The first expert system was called DENDRAL, for Dendritic Algorithm (Bhadeshia, 2015). In the recent decades, artificial intelligence became used in several domains (Russell & Norvig, 2009; Ray, 2004; NRC, 1999). The success was due to: the increasing power of computers, the creation of new links between AI and fields working on similar problems, and a new commitment by researchers to establish mathematical methods and rigorous scientific standards (Russell & Norvig, 2009; Ray, 2004; NRC, 1999; Pamela, 2004).

ARTIFICIAL INTELLIGENCE FIELDS OF APPLICATION

Industry and Robotics

AI is very used in industry. It is thanks to robots that AI have become common in many industries. They are worldwide used: in aviation, object avoidance, transportation, and other industrial domains

(telecommunication, pharmacy, medicine, etc. ...). Artificial intelligence is a theory. Robots are factory-made as hardware. The assembly between these two is that the controlling power behind the robot is a software agent that collects data from the robots 'sensors, then make decision of what to do, and to finish, guides the effectors to act in the physical world (Niemueller & Widyadharma, 2003). Hence, a robot is an artificially intelligent machine.

Economy and Commerce

The advances in the electronic transmission of data, the migration during the past decades of so-called quants and computer wizards to Wall Street and the accessibility of inexpensive but powerful computer hardware and software (Aiken et al., 1991) helped to introduce the AI in economy. Initially knowledge-based systems were considered as tools to allow non-experts to make decisions as effectively as possible for one or more experts in a particular domain (Osorio & Sánchez, 2005). A number of researchers have studied the use of expert systems in accounting, tax and auditing (Michaelsen & Messier, 1987). Also, AI helps take a decision using multistage optimization models described in Figure 2 (Jiménez et al. 2005).

Education

AI systems are spread in the education sector as well; for example, in intelligent tutoring systems, language tutoring and etc. (Lawler & Yazdani, 1987). Some claim that in the domain of education, the procedures and the tools are various. But it is in the pedagogical techniques where the problem lies. AI can provide some solutions to this complication (Obenson, 1989) including computer-assisted education and teaching.

Information Systems

We define an information system (IS) as computer based system, which can access a diversity of

Figure 2. Scenario trees for multiperiod optimization

computer-stored or generated base information, and select to process that information as to offer particular information to help planners and management in their decision-making (Wiederhold, 1991). Artificial intelligence brings to the IS technical knowledge representation to concept bases of practical knowledge and useful learning methods to reuse the systems (Rolland & Florry, 1990).

Data Mining

In general, data mining is the study of observational information sets to find unanticipated relationships, and to summarize the information in original methods that are both comprehensible and beneficial to the data owner (Hand et al, 2001). AI and DM can expand future military information systems.

SOME ARTIFICIAL INTELLIGENCE TOOLS

In this section, some of the artificial intelligence tools is presented and special attention is given to fuzzy logic and artificial neural networks.

Fuzzy Logic: History and Principles

The fuzzy logic is a set of mathematical principles (Cormier, 2014) proposed by Zadeh, in 1965.

It has progressively been extended in order to handle the notion of incomplete truth (Novák et al., 1999). The variables in mathematics generally take numerical values, whereas in fuzzy logic applications, the non-numerics are frequently used to ease the expression of rules and facts (Zadeh et al. 1996).

A fuzzy set is characterized by a function which assigns to each object a grade of membership ranging between zero and one. The notions of inclusion, union, intersection, complement, relation, convexity, etc., are extended to such sets, and various properties of these notions in the context of fuzzy sets are established (Zadeh, 1965). Fuzzy logic has been practical in several fields. The high-speed train in Sendai was the first recognized application (Kosko, 1994) also in recognition of hand written symbols in Sony pocket computers; flight aid for helicopters; etc. (Bansod et Al., 2005).

Figure 3. Example of classical representation
Source: Cormier, 2014

Classical logic has two conditions: TRUE or FALSE. An example is exemplified in Figure 3, whereas another example of fuzzy variables is represented in Figure 4.

There are two techniques in fuzzy logic: the Mamdani method and the Sugeno method. The Mamdani method is the mostly used. This technique follows four steps (Cormier, 2014): Fuzzification of input variables, Rules Evaluation, Aggregation of outputs of the rules and Defuzzification.

The fuzzification step takes the crisp inputs and determines the degree to which these inputs go to each of the right fuzzy sets (Iancu, 2012).

The fuzzy rules, are a series of if and then. They state a set of fuzzy relations between inputs and outputs (Balazinska et al, 2002). For example, the possible rules for a house fan control system having one output (fan speed) and two inputs (temperature and humidity) are:

1. If x is A1 Or Y is B1 THEN z Is C1
2. If x is A2 And Y is B1 THEN z Is C2
3. If x is A3 THEN z Is C3

μ_F is called the membership function MF. It is represented by its formula. Here is a list of some famous MFs (Chen, 2013): Triangular MFs,

Figure 4. Fuzzification of the variables of house fan system

Figure 5. Membership functions of one dimension
Source: Chen, 2013

Trapezoidal MFs, Gaussian MFs, and Generalized bell MFs.

Then, using the membership values determined in fuzzification, the rules are calculated giving the compositional rule of inference. The fuzzified inputs are applied to the antecedents of the fuzzy rules. If a particular fuzzy rule has numerous antecedents, the fuzzy operator (AND or OR) is used to get a single number that characterises the outcome of the antecedent evaluation. To evaluate the disjunction of the rule antecedents, one uses the OR fuzzy operation. The classical fuzzy operation union is used by the Equation 1:

$$\mu_{A \cup B}(x) = \max \{ \mu_A(x), \mu_B(x) \} \quad (1)$$

To calculate the conjunction of the rule antecedents, the AND fuzzy operation intersection is applied using the Equation 2:

$$\mu_{A \cap B}(x) = \min \{ \mu_A(x), \mu_B(x) \} \quad (2)$$

The aggregation of outputs gives one particular fuzzy set (see Figure 6).

The Defuzzification step is to perform the following functions (Iancu, 2012):

1. A scale planning that converts the range of values of output variables into equivalent universes of discourse.
2. Defuzzification, which produces a non-fuzzy control action from an inferred fuzzy control action. There are many different approaches of defuzzification (Leekwijck & Kerre, 1999). We mention, COG (center of gravity), the AI (adaptive integration), CDD (constraint decision defuzzification), BADD (basic defuzzification distributions), COA (center of area) and ECOA (extended center of area). So, the input for the defuzzification procedure is the combined output fuzzy set and the output is a single number. The centroid method is described in Equation 3.

$$\frac{\sum_{x=a}^b \mu_F(x) \cdot x}{\sum_{x=a}^b \mu_F(x)} \quad (3)$$

Artificial Neural Networks: History, Structure and Models

Artificial Neural Networks (ANN) are an attempt at modeling the information processing capabilities of nervous systems (Rojas, 1996). Artificial neural nets have a number of properties that make them an attractive substitute to traditional problem-solving techniques. The two important alternatives to using neural nets are to develop an algorithmic solution, and to use an expert system. The Expert systems are well used by different companies (Gallant, 1993). Neural networks have a notable capability to extract forms and identify trends that are too difficult to be noticed by either humans or other computer systems. A trained neural network can be thought of as an expert in the kind of information it has been given to analyze. This expert can then be used in providing projections given new situations of interest and response what if'' questions. In 1943, the first mathematical model of the biological neuron is suggested by Warren McCulloch and Walter Pitts (McCulloch & Pitts, 1943).

A neuron principally consists of an integrator that makes the weighted sum of its inputs. The result of this sum is at that time transformed by a transfer (activation) function that produces the output of a neuron (McCulloch & Pitts, 1943). A model of the artificial neuron is represented in Figure 8.

An ANN involves of a set of processing elements, also identified as neurons or nodes, which are interconnected. It can be described as a directed graph in which each node i implements a transfer function f_i as follows:

$$y_i = f_i \left(\sum_{j=1}^n w_{ij} x_j - \theta_i \right) \quad (4)$$

a is the internal activity, b is the bias, the $u_1, u_2 \dots u_r$ are the input signals, $w_1, w_2 \dots w_r$ are weights, and the y is the output. The function f is called the activation or squashing function, which maps the internal activity a to a closed interval $[0, 1]$ or alternatively $[-1, 1]$. An example of the

Figure 8. A simple model of an artificial neuron
Source: Ali & Schmid, 2004

activation function is the uni-polar sigmoid function, which has the expression in Equation 5.

$$f(a) = \frac{1}{1 - e^{-a}} \quad (5)$$

There are other activation functions (Karlikand & Olgac, 2010). Also, there are different neural architectures: the single-layer feed-forward networks, multilayer feed-forward networks, and the recurrent networks (Hayken, 2008) presented in Figure 9 (Jain et al., 1996).

The disadvantage of an ANN is its black box quality; it presents results without any description of the procedure. Additional current weaknesses

of ANN consider also the computational resources that are essential and the lack of standard software (Sargent, 2001).

Fuzzy-Neural Network

Neuro-fuzzy representation is concerned with the extraction of models from numerical data representing the behavioural dynamics of a system. Models like these have important functioning predictions of system performance and system control (Jang & Sun, 1993; Takagi & Hayashi, 1988; Chai et al, 2009). One way to combine the two approaches is to use neural networks to replace each component of a system of fuzzy control. The other is the serial or the parallel connections.

Figure 9. Different architectures of ANN

Figure 10. Example of series connection of a neural network and a fuzzy system

Genetic Algorithms

Genetic algorithms are algorithms for optimization (Montana & Davis, 1989). In a genetic algorithm, a population of candidate solutions (called individuals, creatures, or phenotypes) to an optimization problem evolves into better or more capable solutions. Each one of these candidate solutions has a given number of properties (its chromosomes or genotype), which can be mutated, modified, and altered. Typically, the solutions are represented in binary, but other encodings are also possible (Darrell, 1994). During each generation the structures in the present population are rated for their efficiency as solutions, and on the basis of these evaluations, a new population of candidate structures is produced by means of particular genetic operators such as mutation, cross over and reproduction (Oke, 2008). The steps are described in Figure 11 (Orsay University, 2013).

Simulated Annealing

The goal behind creating Simulated annealing (SA) is the global optimization problem of locating an excellent approximation of the optimum of a function in a large search space. The travel salesman problem is one of classic optimization problems. Scott Kirkpatrick, C. Daniel Gelatt, and Mario P. Vecchi used the algorithm on traveling salesman problems, to test the power of simulated annealing (Kirkpatrick et al., 1983). It has also been practical on the problem of finding the ground state of a spin glass (SG). (Soukoulis, 1985; Grest et al. 1986; Guo, 1990). For a finite problem, the possibility that the simulated annealing algorithm terminates with a global optimal solution approaches 1 as the annealing schedule is extended (Granville, 1994).

Thanks to its robustness, SA turned out to be efficient in many fields such as the training of ANNs with structured learning (Wiley & Sons Inc., 1995). Hence, ANN does not need a training set; since the ANN gradually learns new skills or improves existing ones by earlier experience (Ledesma et al. 2013).

Figure 11. Genetic algorithms steps

Swarm Intelligence

Swarm intelligence is an artificial intelligence discipline, (Blum & Li, 2008; Beni & Wang, 1989). It is designed by intelligent multi-agent systems, and the design is inspired by the behavior of some social insects (Blum & Li, 2008) and animals. The particle swarm optimization (PSO) has the purpose of managing problems in order to find a best solution that can be represented as a surface point or in an n-dimensional space (Parsopoulos & Vrahatis, 2002; Clerc, 2006). The bees algorithm is another algorithm designed by Pham and his co-workers in 2005 (Pham et al., 2005) and has gradually enhance its power in the following years (Pham & Castellani, 2009).

FUTURE RESEARCH DIRECTIONS

Future of AI

Looking into the future, there is a real possibility that AI will introduce extremely intelligent artificial agents. This would be revolutionary as we could have machine assistance in every field. AI machines will have certain capabilities such as: Self-improvement: intelligence amplification, strategy development: planning, forecasting, prioritizing and social abilities: social and psychological modeling, manipulation, rhetorical persuasive ability.

Ethics of AI

The potential existence of a machine that could exceed the human intelligence has created some ethical issues. For example, who takes the blame, when an AI system fails at its assigned task: the programmers, or the end-users (Gelbukh & Monroy, 2005)? Also, some scientists, such as Dr. Hugo de Garis of Utah State University, feel that the artificial brains will not be controllable (Roberts, 2014). Moreover, some say that people may lose their jobs, and be deprived of their personal lives (Cormier, 2014). According to (Singer & Friedman 2014), privacy is certainly serious issue in AI fields. More ethics span law, public policy, professional ethics, and philosophical ethics, and will require expertise from computer scientists, legal experts, political scientists, and ethicists.

CONCLUSION

Scientists' efforts and quest to solve the riddle of the human brain's intelligence have been documented throughout history. Artificial intelligence is an attempt to create entities as intelligent as humans or more. We have defined in this paper

the Artificial Intelligence, taken a short look at its history and listed the domains of its applications. We also, detail well known algorithms that present a great deal of interest in the optimization in many domains. Also, some tools of AI are presented.

A

KEY TERMS AND DEFINITIONS

Artificial: Description of an object made by human beings and not a naturally.

Dendritic Algorithm: A classification algorithm based on the functioning of natural immune dendritic cells.

Intelligence: The ability to acquire, learn and apply knowledge and skills.

Spin Glass: An optimization problem, NP-complete problem (non-deterministic polynomial time complete) in three dimensions.

Artificial Neural Networks

Steven Walczak

University of South Florida, USA

INTRODUCTION

Artificial neural networks (ANNs) is a subfield of machine learning within the research domain of artificial intelligence (see Artificial Intelligence, this volume). Research in developing ANNs started after McCulloch and Pitts (1943) proposed a mathematical model of neuronal activity in the brain and Hebb (1949) created a reinforcement based learning mechanism to explain learning in the human brain. Rosenblatt (1958) then created a computational model of brain processing elements called perceptrons and ANN research started in earnest. The goal of ANN research is to develop machine learning systems that are based on a biological model of the brain, specifically the bioelectrical activity of the neurons in the brain.

ANNs are a popular solution method in numerous domains including: business (Tkáč & Verner, 2016; Wong, Lai, & Lam, 2000), engineering (Ali et al., 2015; Bansal, 2006), and medicine (Reggia, 1993; Yardimci, 2009). Research and development with ANNs continues to be highly productive with the quantity of articles published in this subfield increasing annually. Using the search query *artificial neural network* on a university article database search produced 27,736 articles from 1985 to 2000 and 203,328 from 2001 to 2016 with over 51 percent of the publications appearing from 2011 to 2016; indicating a tenfold increase in ANN articles published over the same amount of time (16 years) and the trend continuing to accelerate.

It is important to understand the terminology used to discuss ANN architectures. A sample ANN architecture for a supervised learning multi-layer perceptron is shown in Figure 1. Modern ANNs are composed of:

- A layer of input elements also called the input vector, representing independent variables,
- Optionally, one or more hidden processing layers,
- Weighted connections between nodes in adjacent layers, and
- An output layer of one or more elements, representing the dependent variable(s).

Every processing element or neurode in a layer is connected to all processing elements in the next layer, with input neurodes connected to hidden layer neurodes etcetera, until the neurodes in the last hidden layer are connected to the output layer neurodes. These connections all carry a value, commonly called a weight, that is adjusted to permit learning. It is possible for an neurode to not be fully connected to the subsequent layer, but to be connected selectively to one or more neurodes in the following layer. Some ANN architectures also have weighted connections from a layer to not only the next layer, but also to one or more subsequent layers of neurodes.

What types of research problems are amenable to an ANN approach? Essentially, ANNs are intelligent pattern recognition machines. Thus, any problem which may be defined as a pattern recognition problem is suitable for ANN solutions. This includes all types of classification problems and also most prediction problems, such as time-series forecasting or medical diagnosis. Additional research has shown that ANNs may be used as a tool for evaluating medical or business decision making heuristics (Walczak, 2008).

Figure 1. Supervised learning ANN architecture (only a few connection weights shown)

BACKGROUND

Research on ANNs and development of ANN applications started out strongly throughout the 1960's following Rosenblatt's (1958) discovery of perceptrons. Early work in ANNs used perceptrons and multiple layer perceptrons, that used a supervised learning rule to adjust connection weights based on the difference between the desired output and the output produced by the perceptron. Other learning rules were also developed including the ADALINE (ADaptive LINEar Element) and MADALINE (Multiple Adaline) (Widrow, 1964).

Minsky and Papert (1969) demonstrated limitations of simple perceptrons, specifically difficulty in solving the exclusive or problem. A simple perceptron is defined as an ANN where the input layer is connected directly to the output layer with no intervening layers. The backpropagation algorithm, also referred to as a multi-layer perceptron, was created in 1974 (Werbos, 1974), enabling rapid training of multilayer perceptrons (MLPs) and thus overcoming the limitations identified by Minsky and Papert. In the late 1970's and early

1980's ANN research exploded and has continued to increase ever since.

Processing Criteria of ANNs

As mentioned in the introduction, ANNs are composed of processing elements called neurones arranged in layers that are connected. In addition to the physical elements of the ANN, there are several soft processing criteria that are also important to understand. The learning rule is the algorithm that permits the ANN to learn, typically through updating of connection weights. The learning rate is how fast and how large updates are made to connection weights. Typically the learning rate starts out large enabling rapid changes in the weights and subsequent output values. The rate gradually decreases over time so that changes become smaller and smaller. A random adjustment of the rate upward is randomly performed to prevent the ANN from settling into a local minimum in the solution surface and to move towards the global minimum.

As noted in Figure 1, all neurodes past the input layer will have multiple input connections from the previous layer. Each neurode uses an aggregation function to collect the weighted input values. Common functions may include: summation, minimum value, maximum value, mean, mode, or median. Other functions are possible and may be defined by the ANN developer.

Because ANNs originally modelled the neuronal processing of the human brain, each neurode in the ANN also has a transfer function to mimic the firing or activation of brain neurons. A typical transfer function is sigmoidal, hyperbolic tangent, or Gaussian but again any function may be defined by the ANN developer to use for transferring values to the next layer. All of these soft processing criteria are involved in producing learning within the ANN.

Types of Learning

ANNs are capable of producing complex models of highly nonlinear solution surfaces through machine learning. Learning in ANNs is performed through adjustment of the connection weights. The algorithms for how to select the update values and updating the weights is an ongoing area of research in the study of ANNs. Learning algorithms for ANNs are commonly classified as being either unsupervised learning or supervised learning methods.

Unsupervised learning implies that the solution to a problem is already contained within the data being used to train the ANN. This type of learning is typically used in image classification research, such as detecting anomalies in medical images, analyzing seismographic data, and other visually and auditorily oriented data. A few examples of unsupervised learning algorithms are the self-organizing map (SOM) sometimes called Kohonen networks (Kohonen, 1990) and adaptive resonance theory (ART) (Carpenter & Grossberg, 1987). A small sample SOM network is shown in Figure 2. Since unsupervised learning training networks do not require a known value to

Figure 2. A small, 4X4 SOM network

calculate their error, they compare their current state against the state of the input vector and adjust weights around the current Kohonen neurode that is the best matching unit. Thus a neighborhood of weights gets adjusted with each training sample.

The advantage of unsupervised learning over supervised learning is primarily in the lack of a requirement for data that already has a correct classification as the unsupervised ANN learns the proper classification strictly from the input data values. A disadvantage from supervised learning is that the solution is portrayed in the Kohonen network or other neurode network attached to the input nodes and its values are left up to the interpretation of the researcher.

Supervised learning indicates that a known solution to the problem must already exist for all training data examples. Thus, supervised learning is popular for solving problems when historic data sets with known outcomes exist. Supervised

learning may be used to perform classification, as with unsupervised learning, but may also be used to create predictive models, such as time series forecasting or medical diagnosis. The most well-known supervised learning rule algorithm is backpropagation (Werbos, 1974). Backpropagation trained ANNs have been shown to be a universal approximators (Hornik, Stinchcombe, & White, 1989; White, 1990), meaning they can heuristically approximate any function or solution surface.

Research on how to improve the backpropagation algorithm was rampant in the late 1980's and early 1990's and continues today. Various algorithms other than backpropagation now exist for performing supervised learning and include radial basis functions (Lowe & Broomhead, 1988), learning vector quantization (Kohonen, 1988), probabilistic (Specht, 1990), general regression (Specht, 1991), and fuzzy ARTMAP (Carpenter et al., 1992). Each learning rule attempts to address a perceived shortcoming of the backpropagation algorithm, such as radial basis function trained ANNs being more resilient when only small or incomplete training examples are available (Barnard & Wessels, 1992) and general regression ANNs converging faster when a very large number of training examples are available (Specht, 1991).

BUILDING ANNs

Theoretical research in ANNs typically examines ways to speed up learning through the development of new learning algorithms or ANN architecture schemas. Applied research investigates the utilization of ANNs for solving difficult domain problems.

For applied research, ANNs must be developed and tested against existing solution methods. As indicated above, ANN designers face numerous decision to determine the optimal ANN design, both physical architecture and soft processing criteria. Numerous tutorials and guidelines exist (see Additional Readings) and therefore a detailed

description of ANN development will not be done here, but a quick set of decision considerations needed is given:

1. Based on the type of problem, determine supervised or unsupervised methodology.
2. Based on specifics of problem and data available, select learning algorithm to train the ANN (e.g., backpropagation or radial basis function).
 - a. Multiple algorithms may modeled independently.
 - b. Use comparative analysis to select the optimal performing ANN algorithm
3. Determine ANN architecture.
 - a. Number of layers (if applicable, for some supervised learning algorithms).
 - i. The number of layers gives insight into the complexity of the solution surface being modeled.
 - b. Number of nodes per layer.
 - i. Too few nodes will not allow the ANN to adequately model complex solution surfaces.
 - ii. Too many nodes will enable the ANN to memorize the training data and may produce suboptimal generalization performance.
4. Specify (if appropriate for learning algorithm) the aggregation function, transfer function, and learning rate.
5. Train the ANN.
6. Validate the trained ANN using data not used in training (out of sample).
7. Repeat until the best performing ANN architecture and learning algorithm are determined.

Fortunately, numerous ANN shell tools exist to facilitate the rapid development of numerous ANN solution models. Some examples include: MATLAB® (built in ANN shell), IBM® SPSS® (a separate add-on), NeuralWare® NeuralWorks products, Stuttgart Neural Network Simulator (SNNS), Emergent, and Neural Lab, among many others

(see the websites <http://www.neural-forecasting.com/software.htm> and https://grey.colorado.edu/emergent/index.php/Comparison_of_Neural_Network_Simulators, which both maintain lists of ANN shell tools). These shell tools enable researchers to select which type of ANN, supervised or unsupervised learning, and typically provide a choice of several different learning algorithms to match the learning type selected. The research then enters in the number of layers (if applicable) and quantity of neurodes per layer. Several also allow the developer to select soft processing criteria such as the aggregation and transfer functions.

ADVANTAGES AND DISADVANTAGES OF ANNs

One question researchers should ask is: why should I use an ANN versus some other proven methodology? A similar question would be should Copernicus ever have examined non-geocentric models of the solar system? Recent research has called for the investigation and utilization of ANNs in previously untried domains (DeTienne, DeTienne, & Joshi, 2003; Smith & Gupta, 2000). ANNs provide an alternative and often better framework for research seeking to solve complex problems.

Advantages

ANNs have generally been shown to be similar to parametric statistical methods for linear problems and to outperform parametric statistical methods on nonlinear problems (DeTienne, DeTienne, & Joshi, 2003; Walczak, 2012; Warner & Misra, 1996), indicating that more reliable results are achievable through ANNs than traditional statistical methods. Perhaps this is an unfair comparison as one of the significant advantages of ANNs over traditional statistical methods is that they are nonparametric. This means that the data used for training and subsequent use of ANNs does not need to satisfy any external statistical criteria such as being normally distributed or have a normal

error distribution. Any data may be used so long as it is meaningful to the problem solution.

An obvious advantage of ANNs is that they utilize machine learning to learn the solution surface for any domain problem. This indicates that they are capable of robust learning and can reliably approximate the solution surface for any appropriate problem (Hornik, Stinchcombe, & White, 1989). Once ANNs are trained the weights are typically locked when producing a real-world ANN application. This may then require periodic re-training of the ANN to capture changes in the population for classification problems or changing dynamics of the problem for prediction problems, such as periodicity of time series effects. ANNs are capable of learning any solution surface.

Another advantage to using ANNs in research is that once they are trained, the final model is resilient to noise in out of sample input data. Depending on the learning algorithm used, outliers and error prone data may be dealt with differently, but the ANN will still give a reliable approximation to the current data's location on the solution surface. Keep in mind that this advantage is for out of sample data only and that for most learning algorithms, relatively error free training samples are required to enable optimal learning.

Disadvantages

The biggest disadvantage to using ANNs for research and applications is their black box nature. Unlike the artificial intelligence technique of expert systems which can offer an explanation of the reasoning used to provide their answers, ANNs have no such explanation facility. The output is a result of the given input, but no other explanation of the reasoning or relationship of individual independent variable contribution is available. Various techniques have been developed to try and overcome the black box nature of ANNs. These include leave on out strategies that eliminate select variables from an ANN to determine the effect of that variable on the solution (Walczak, 2008), other methods to try and determine input variable

importance (Gevrey, Dimopoulos, & Lek, 2003; Paliwal & Kumar, 2011), and automated methods to generate regression-like equations from developed neural networks such that the coefficients associated with each variable may be evaluated (Hayashi, 2013; Tickle et al., 1998). Both of these techniques are labor intensive and as the size of the ANN grows, both through adding additional input variables and also when increasing the number of weighted connections through the addition of either additional hidden layers or additional neurodes within any of the layers, the regression equation techniques become more problematic.

One of the advantages of ANNs may also be viewed as a disadvantage. Since ANNs learn, they will find a way to map any input data into a solution surface. This means that anything can be learned even if it is meaningless. This introduces the problem of input variable sensitivity. There are two schools of thought on the types of input variables that may be used in ANNs. Because ANNs are learning, the first school believes that any number of relevant (and possibly irrelevant) variables may be given to the ANN as input and the ANN will learn which ones are meaningful. While this is true to an extent, the fact remains that all input influences the output of the ANN to a greater or lesser degree and even a small influence coming from an irrelevant variable may be sufficient to hinder the overall classification or prediction performance of the ANN. The second school believes that selecting the input variables is critical to performance and that only uncorrelated variables (Smith, 1993) which are somehow relevant to the solution (Tahai, Walczak, & Rigsby, 1998) should be used. Thus care must be taken to select relevant variables, perhaps through consultation with domain experts, and then test these variables to make sure none of them are highly correlated with each other.

A similar issue is the population demographics of the training data sets. Again, the learning capability of ANNs affects the answer. The choices are: balanced training sets with equal numbers of

each class present (Zhou & Liu, 2006), real-world training sets where the training set population percentages are similar to the real world (Wilson & Sharda, 1994), or other imbalanced or random sets. Balanced or real-world representative training sets are both usable as long as the real world population classes are not too disparate in membership size. This is because the ANN will learn to maximize its results and if one class of the population is only a very small percent of the overall population, then for a small number of classes the ANN may be able to optimize its classification results by ignoring the small class. If however this class is very important, such as a positive medical diagnosis for a disease, then it cannot be safely ignored. This problem decreases as the number of classes increase, as long as one class does not dominate the other class representations. Assuming all outcomes are equally important regardless of real-world population percentages, balanced training sets should be used to enable the ANN to adequately identify the correct solution surface.

A former issue with ANNs is the training time, which on older computers could take days or weeks to enable adequate learning to take place. As processor speeds have increased over time, this disadvantage no longer truly exists except for very large ANN architectures with thousands of neurodes and massive input data (big data).

A final issue with use of ANNs as real-world applications is an ethical one. Because ANNs operate as black boxes, what are the ethical and legal responsibilities of professionals who utilize the ANN's results? Furthermore, legal standards, especially in healthcare, mandate specific requirements for developers of ANN systems which include: repeatability, reliability, and performance (Lisboa & Taktak, 2006). Users of ANNs should be able to rely on the results of the ANNs as expert consultants, but should still use their own knowledge and discretion in interpreting the ANN's recommendations or results, as with any other computerized system.

Table 1. Examples of recent ANN research

Domain	ANN Types	Description	Reference
Agriculture	MLP	classify land cover images	(Heremans, Suykens, & Van Orshoven, 2016)
Business	MLP	predict manufacturing throughput	(Huang et al., 2016)
Finance	MLP recurrent	predict Chinese stock market predict stock, commodity, forex	(Sun et al., 2016) (Hussain et al., 2016)
Engineering	MLP	power outage prediction	(Tahir & Saqib, 2016)
Geology	MLP	predict landslides	(Bui et al., 2016)
Medicine	MLP MLP	predict morbidity severity predict length of stay	(Majd et al., 2016) (Tsai et al., 2016)

APPLICATIONS OF ANNs

ANNs are used across numerous disciplines to accomplish a wide variety of tasks. Table 1 shows a small sample of recent usage of ANNs appearing in the literature.

FUTURE RESEARCH DIRECTIONS

The biggest need for ANN researchers is to have ANNs recognized by the scientific community as a valid research methodology. Publications regularly appear to introduce the novel idea of ANNs as a research method across various domains (DeTienne, DeTienne, & Joshi, 2003; Smith & Gupta, 2000; Vitek, Iskander, & Oblow, 2000). Since numerous studies have already been mentioned that demonstrate the superior performance of ANNs over traditional parametric statistical techniques, this argument should not be hard to make, thus opening the door for additional ANN research across a much wider variety of research domains.

With the increasing importance of big data research, new research in ANNs is needed to examine how ANNs can learn quickly from big data training sets. Additional research will continue to examine new architectures.

Ensembles of ANNs, where one ANN produces the input for a subsequent ANN and the combination of ANNs creates a classification or prediction system is a growing area of research interest (West, Dellana, & Qian, 2005; Zhang &

Berardi, 2001). This ensemble combination of ANNs enables better classification of data when classification criteria across is independent across multiple categories within the data. Recurrent ANNs (RNNs) are ANNs where connections between units provide for directed cycle which enables the RNN to maintain a temporal state of the data. Although the idea of RNNs has been around since the late 1980's (Pineda, 1987), there has been a resurgence in interest recently in using RNNs for various tasks including speech and handwriting recognition.

Similar to combining ANNs with other ANNs into ensembles, there has been a growing research interest in combining ANNs with other statistical and artificial intelligence methods to create more robust learning environments (Walczak, 2012) and consequently better generalization from the trained ANN to a real-world application. Future research will continue to focus on integrated systems with incorporated ANNs (Pandey & Mishra, 2009), to enable the strengths of each integrated component to overcome shortcomings of the other components.

Deep learning ANNs have surfaced as a new research paradigm for the 2010's and into the future (Arel, Rose, & Karnowski, 2010). These deep learning ANNs enable the use of multiple types of data and data representations to gain a better understanding of classes (Schmidhuber, 2015). Successes in deep learning are already being demonstrated in image and speech recognition ANN systems (Ciresan et al., 2012; Hinton et al., 2012).

CONCLUSION

ANNs are a method for performing complex pattern recognition using machine learning techniques. The learning capabilities of ANNs make them robust and enable them to approximate arbitrary solution surfaces with a high degree of reliability (White, 1990). ANNs are applied across a wide variety of domains to solve numerous complex problems, but further advances into new fields are still needed.

The strengths of ANNs include: they are based on machine learning and thus able to learn arbitrary solution surfaces, they are nonparametric and may thus be applied to a larger variety of problems and data than traditional parametric statistical methods, and once trained they are resilient to noise in the data. While ANNs also have some perceived disadvantages, it is possible to overcome these disadvantages and new research in ANN ensembles and integrated systems that include an ANN component may further alleviate these perceived problems.

Because of their rich modeling capabilities based on machine learning and general superiority over traditional statistical methods, ANNs should become a de facto standard in any researcher's methodology toolbox.

KEY TERMS AND DEFINITIONS

Backpropagation: A learning method for ANNs that uses the relative error of a given output or set of outputs (epoch) that is propagated back through the ANN and used to adjust all weights on the connections between neurodes.

Epoch: A subset of training examples used as a group to determine average error for the ANN.

Neurode: A processing element within an ANN that simulates a single neuron in the brain.

Supervised Learning: A method used to train ANNs in which a training sample with known outcomes is used to enable the ANN to learn. The known outcome values are used to calculate an error term between the known or desired output and what is produced by the ANN to let the ANN know how to adjust its connection weights to minimize the relative error.

Unsupervised Learning: A learning method used to train ANNs where the ANN learns directly from the input values given to determine adjustments in connection weights.

INTRODUCTION

In recent years, emotion recognition has become a hot topic in human-computer interaction. If computers could understand human emotions, they could interact better with end users (Peter & Beale, 2008). In psychology, emotion is defined as a complex state that consists of a subjective experience (how we experience emotion), a physiological response (how our bodies react to emotion), and an expressive response (how we behave in response to emotion) (Smith & Lazarus, 1990). Emotion expression includes not only facial expression but also vocal and postural expression. The observable aspects of emotion (physiological and expressive components) might be able to be used as indicators of emotional state, such as facial expressions, speech, physiological parameters, gestures, and body movements (Peter & Beale, 2008). As the common use of modalities to recognizing emotional states in human-human interaction, various clues have been used in affective computing, such as facial expressions (e.g., Kenji, 1991), physiological signals (e.g., Picard,

Vyzas, & Healey, 2001), linguistic information (e.g., Alm, Roth, & Sproat, 2005) and acoustic features (e.g., Dellaert, Polzin, & Waibel, 1996). Other than that, it is feasible to recognize specific affective states using gait.

To investigate how gait features are effective in characterizing and recognizing emotions, gait features were used for modeling to identify different emotions. By utilizing 59 participants' gait data with emotion labels, machine learning models are trained to detect individual emotion (Li et al, 2016).

BACKGROUND: GAIT AND EMOTION

Walking is one of the basic and important components for the body posture and movement, and psychological research found that affective states can be identified by gaits (Montepare, Goldstein & Clausen, 1987). People in different emotional states could walk in different speed and show different gait patterns (Strike, Mohiyddini & Carlisle, 2009). Human can perceive others' emotion from

gait or posture in daily life. For example, people in fear may shrink his shoulder, and sad ones might lower his head and walk slowly (Roether, Omlor & Christensen, 2009). Even when gait was minimized by use of point-light displays, which meant to represent the body motion by only a small number illuminated dots, observers still could make judgments of emotion category and intensity (Atkinson, Dittrich, Gemmell, & Young, 2004).

Since Montepare et al. (1987) firstly demonstrated that gait relates to emotions, there have been a lot of researches focusing on the relationship between gaits and emotions. Krieger et al. (2013) found that gait, cognition and emotion are closely related. Applying sparse regression, Roether et al. (2009) extracted critical emotion-specific posture and movement features depended only on a small number of joints. Gross et al. (2011) identified the movement characteristics associated with positive and negative emotions experienced during walking. Destephe et al. (2013) assessed the differences between the expression of emotion regarding the expressed intensity. Characterizing human walking patterns by some kinematic cues, Hicheur et al. (2013) produced the avatar animation whose emotions could be recognized by human observers. In particular, by using data mining technique, much research has been done to recognize emotions automatically by analyzing subjects' gait. The accuracy of classifying distinct emotional states was 60~89% (Janssen, Schollhorn & Lubienetzki, 2008; Hicheur, Kadone, Grezes & Berthoz, 2013; Gunes, Shan & Chen, 2015; Clark, Pua & Pua, 2012).

Recently, it has also been reported the application of Kinect in the medical field. Lange et al. (2011) used Kinect as a game-based rehabilitation tool for balance training. Yeung et al. (2014) found that Kinect was valid in assessing body sway in clinical settings. Kinect also performed well in measuring some clinically relevant movements of people with Parkinson's disease (Galna, et al., 2014).

MAIN FOCUS: NON-CONTACT GAITS INFORMATION

A

Two Issues of Gaits Information

By exploring the researches and experiments on identifying humans' emotions from gait, there are two main foci: one is the way of data acquisition, the other is the features for describing gaits. These two foci are very important to identify human emotions automatically. Some works used high-speed cameras to get a video of gaits (Das & Meher, 2013; Rokanujjaman, Hossain & Hossain, 2014). The collected gait data lacked of some information such as joints of subjects' ankles, shoulders, etc. Some works employed 3D motion capture systems including wearable devices. While these wearable devices could help us acquire gait precisely, subjects with wearable devices may be uncomfortable, and emotions may be affected while walking (Roether, Omlor, & Christensen, 2009; Karg, Kuhnlenz, & Buss, 2010). The situation may be even worse for some people such as elderly adults, children, and mental patients. Thus, it is very important to acquire gait data in the way of non-contact. In addition, the cost is another considerable factor. The gait information recording technologies such as marker-based motion tracking system had already made it possible to automatically recognize the emotional state of a walker (Karg, Kuhnlenz, & Buss, 2010), however, because of the high cost of trained person, technical equipment and maintenance (Pogrzeba, Loreen, Wacker, Markus, Jung, Bernhard, 2013), the application of these non-portable systems were seriously limited.

Microsoft Kinect

The Microsoft Kinect is a low-cost, portable, camera-based sensor system, with the official software development kit (SDK). As a marker-free motion capture system, Kinect could continuously monitor three-dimensional body movement patterns, and

is a practical option to develop an inexpensive, widely available motion recognition system in human daily walks. The validity of Kinect has been tested in the studies of gesture and motion recognition. Kondori et al. (2011) identified head pose using Kinect, Fern'ndez-Baena, Susin and Lligadas (2012) found it perform well in tracking simple stepping movements, and Auvinet et al. (2015) successfully detected gait cycles in treadmill by Kinect. In Weber et al.'s (2012) report, the accuracy and sensitivity of kinematic measurements obtained from Kinect, such as reaching distance, joint angles, and spatialtemporal gait parameters, were estimated and found to be comparable to gold standard marker-based motion capture systems like Vicon. Since emotion could be expressed in gaits, and Kinect has been found a valid instrument to record gait, which motivates us to recognize emotion by gaits acquired by Kinect. We hypothesize that gaits information recorded by Kinect in the form of coordinates of the body joints, and the states could be recognized through machine learning methods based on gait.

Method

We have made several changes to the experiment design differing from previous work. In previous studies, participants were often required to recall a past situation or imagine a situation associated to certain affect while walking (Roether, Omlor, & Christensen, 2009; Gross, Crane, & Fredrickson, 2012), in which the induced emotional was too strong. The first change is that we chose a moderate way—watch videos—to induced people's emotions.

Secondly, the participants were instructed to walk naturally. Compared to requiring participants to walk with certain emotion (Westermann, STAHL, & Hesse, 1996), the walking condition of participants in our study was more ecological.

The experiment has been completed in a footpath with one meter wide and six meters long. At both ends of the footpath, we set up a Kinect sensor respectively to record walkers' gait information. Figure 1 sketches the experiment's scene, in which the dark area is the footpath. Because the minimum and maximum photographic distance of each Kinect's sensor is 1m and 3m respectively (Han et. al., 2013), subjects are instructed to walk inside the district not near to the sensors.

59 healthy graduate students (32 females) are recruited to take part in this experiment. Their average age is 23, and they have no injuries, illnesses or other condition influence their gait patterns. Every participant will first walk back and forth for 2 minutes in the walking district, evaluate his or her emotional state: angry or happy, and give a score: 1 to 10. Then, they will watch a short video for arousing one certain emotion like joy or angry, and continue walking around the footpath for 1 minute. At last, they assess themselves how happy or angry they are by presenting two scores (1 to 10) to evaluate their own emotional state finishing watching the video and finishing the second walking.

The above experiment will be conducted twice. In the first experiment, subjects' happy emotion will be aroused by a shot video full of jokes after walking with certain natural emotion for two minutes, while participants' negative emotion

Figure 1. The experiment's scene and walking district: the footpath is one meter wide and six meters long, and two Kinects are set up at both ends

like anger will be aroused in the second experiment. In addition, there is an interval of at least one day between these two experiments to avoid the emotional interference.

Data Collection and Processing

The whole procedure for identifying emotions from gait information just like a general machine learning process, it consists of four parts: Collecting Data, Data preprocessing, Feature extraction, Modeling and Classification.

The data collected from natural walking. With the Kinect cameras placed at the two ends of the footpath, participants' gait information was recorded as video on 30Hz frame rate. Each frame contains 3-dimensional information of 25 joints of body, including head, shoulders, elbows, wrists, hands, spine (shoulder, mid and base), hips, knees, ankles and feet, as shown in Figure 2.

During our experiment, all the frames recorded by one Kinect sensor were integrated consequently

in a '.txt' file. Figure 3 shows coordinate tracks of some different joints: the base of the spine (black solid), right ankle (red dashes), right wrist (rose-red line) and right shoulder (blue dash dots) for three different emotion states. And, from these figures, we can find that for different emotional states, tracks of the same joint differ obviously.

The raw data may be noisy, complicated and redundant. To make it clean for further process, it is necessary to run data preprocessing. The operations we take before extracting features, includes 4 steps: data segmentation, low-pass filtering, coordinate translation, and coordinate difference (Li, et. al., 2016).

After data preprocessing, we then run feature selection to acquire important gait features closely related to subject's emotions. Figure 4 shows the procedure of extracting features, in which operations in dotted box are optional because it needs to be verified whether they improve the performance of classification models. Since there are two types of data fractions: front and back parts, and here

Figure 2. Stick figure and location of body joint centers recorded by Kinect

Figure 3. Coordinate tracks of joints in 3 emotional states: the diversity between joints is obvious, and the tracks of the same joint differ slightly in different emotional states

we only describe the procedure to extract features from front, and the same procedure works on the back part.

From data set, we found that each walker completed more than four rounds during experiment, so we get 2880 features of a sample. These features form the set of ones in the frequency domain, and shorted as *FF* (*Features in the frequency domain*). We denote features in the time domain as *FT* (*Features in the time domain*), which are some related kinematic ones too. At last, we calculated their mean and variance. Combined with frame number of this segment, we got 11 features in one walking segment and 44 features in a sample.

Results

Self-Reports of Emotional States

In the current study, for both anger and happiness priming, the emotional state ratings of AP (After priming) I and APII were higher than BP (Before priming). Paired-Samples *t*-test (by SPSS 15.0) showed that: for anger priming, anger ratings before priming was significantly lower than API ($t [58] = 18.98, p < .001$) and APII ($t [58] = 14.52, p < .001$); for happiness priming, happiness ratings before priming was also significantly lower than API ($t [58] = 10.31, p < .001$) and APII ($t [58] =$

7.99, $p < .001$). These results indicated that both anger and happiness priming were successfully eliciting changes of emotional state on the corresponding dimension. In the first round, participants were generally experiencing more anger while walking after video than before video, and the same happened for happiness in the second round.

Classifying Results and Comparison

We used *FF + FT*, *FT* and the “PCA-DFT-PCA” method proposed by M. Karg et al. (Karg, Kuhnlenz, & Buss, 2010) to classify three emotions: Neutral, Happy and Angry. Because there is no evidence shown that a certain classifier method in the machine learning fits for identifying emotions than others (Gunes, & Schuller, 2013), we have tries several classifiers including linear discriminant analysis (LDA) (Martinez, & Kak, 2001), Naive Bayes (Jordan, A., 2002), Decision tree (Quinlan, 1993) and SVM (William, & Teukolsky, 2007) to build our model for classifying and predicts subjects’ emotions from gait. The results of accuracy are shown in the Table 1.

We also tried classifying emotions on different Kinects. Three computational models were built to differentiate anger from neutral state (before anger priming), happiness from neutral state (before happiness priming), and anger from

Figure 4. The flow chart of extracting features in the time and frequency domain

Table 1. The accuracy of different emotion (In %)

Features	Emotion	LDA	NaiveBayes	DecisionTree	SVM
FF+FT	Neutral	60	55	59	68
	Happy	62	59	61	71
FT	Neutral	58	46	53	61
	Happy	61	76	88	76
Karg's features	Neutral	66	49	17	49
	Happy	37	48	91	49
FF+FT	Neutral	53	71	49	34
	Angry	44	17	53	41
FT	Neutral	46	59	54	58
	Angry	46	54	32	48
Karg's features	Neutral	44	52	63	51
	Angry	58	48	45	48
FF+FT	Happy	59	61	55	65
	Angry	63	65	64	70
FT	Happy	61	61	55	60
	Angry	58	59	56	63
Karg's features	Happy	64	53	35	56
	Angry	56	48	67	53

happiness. We trained and evaluated several classifiers, including *Naive Bayes*, *Random Forests*, *LibSVM* and *SMO*, with 10-fold cross-validation. Table 2 shows the accuracy of each classifier in recognizing different emotions. There exists difference between the results of Kinect 1 and Kinect 2, and the accuracy using data recorded by Kinect 1 was better than Kinect 2.

FUTURE RESEARCH DIRECTIONS

The quality of gait recorded by two Kinect cameras were different, which probably meant that we did not perfectly control the illumination intensity of our experiment environment. Therefore, we should pay more attention to the control of conditions in the future. This study presented a feasible method of automatically recognizing emotional states

Table 2. The accuracy of recognizing different emotions (In %) Note: Table entries are accuracies expressed as a percentage. Values below chance level (50%) are not presented.

		Naïve Bayes	Random Forests	LibSVM	SMO
Angry & Neutral	Kinect 1	80.5085	52.5424	72.0339	52.5424
	Kinect 2	75.4237	—	71.1864	—
Happy & Neutral	Kinect 1	79.6610	51.6949	77.9661	—
	Kinect 2	61.8644	51.6949	52.5414	—
Angry & Happy	Kinect 1	52.5424	55.0847	—	51.6949
	Kinect 2	—	51.6949	—	50.8475

from gaits using the portable, low-cost Kinect cameras. It would be worthwhile for future studies to improve this method, to identify certain types of affect more accurately. In our study, the extraction of low-level features from gaits was by heuristic. In fact, people found that different facets of gait patterns may relate to certain dimensions of emotion (such as arousal level or valence) in varying degrees (Pollick, Paterson, Bruderlin, & Sanford, 2001). In future study, we plan to add more features according to the characteristics of the target emotion, for a better utilization of the features in model training. In addition, the future work could use other methods such as time-frequency analysis to identify different emotions.

CONCLUSION

In this paper, we propose a novel method to recognize human emotion from gait data collected by Microsoft Kinects. Different from existing methods, we extracted gait features in both time and frequency domain to classify different affective states: Neutral, Happy and Angry states. Experimental results partly supported our hypothesis: the walkers' emotion states (such as happiness and anger) could be reflected in their gaits recorded by Kinect in the form of coordinates of the main joints of body, and the states could be recognized through machine learning methods based on gait.

Although the current method could only recognize induced emotions, it still demonstrated the potential benefit in application. The automatically recognized emotional arousal could be very useful for decision making, security check and so on.

KEY TERMS AND DEFINITIONS

Affective Computing: It is defined as recognize, interpret, process, and simulate emotion via technologies or devices.

Automatic Emotion Recognition: It is a manner of recognize emotion by using computer technologies such as signal processing, machine learning, and computer vision.

Emotion: It is a manner of nonverbal expression of people's views and attitudes.

Emotion Recognition: Means comprehend or unscramble emotion, usually refer to a social ability of humans.

Emotional Arousal: Which is an emotional reaction induced by certain emotional stimulus.

Board Games AI

Tad Gonsalves

Sophia University, Japan

INTRODUCTION

To date, Artificial Intelligence (AI) has produced a plethora of techniques and algorithms in the field of computer game playing. Escaping from the maze being chased by the enemy, firing shots and dodging missiles, etc. coupled with background music, eerie sounds, and animated colors are some of the AI games that fill modern computer screens. Although the flashy and dazzling computer games are increasingly becoming popular, this chapter deals with the description and analysis of the *classic* AI games, where two players (an intelligent computer program and a human player) sit on opposite sides with the game board in the middle. Examples of such classic AI games are tic-tac-toe, checkers, othello, chess, shogi, go, etc.

The classic games, played by two players on a single board taking turns alternatively are known as zero-sum games with perfect information (Millington, & Funge, 2009). The game can be unfolded in the form of a tree structure and the winning path consisting of legal moves through the tree nodes and branches can be traced using an efficient algorithm called the *MiniMax* algorithm. At the heart of this algorithm is the evaluation function, which gives an estimate of the goodness of a board position. Even complex board games like chess rely on the computation of the evaluation function to determine the best possible move. However, due to the combinatorial explosion of the state space an exhaustive search of the game tree is infeasible. This situation is alleviated by the alpha-beta pruning technique and other heuristic search methods.

Machine Learning (ML) techniques employing Artificial Neural Networks is emerging as a powerful technique in game playing. In some

applications, ML programs learn the evaluation function itself and then compute the winning moves using the *MiniMax* and the alpha-beta pruning algorithms. Some rely purely on the ML methods for mastering the winning strategy while others also use expert knowledge to supplement the ML process.

This chapter introduces the classic two-player zero-sum (the end result of the winner-loser score is zero), deterministic board games and explores some of the classic AI algorithms for game playing. In particular, it describes the game-tree, the *MiniMax* and the alpha-beta pruning algorithms for searching for the winning moves in real-time. It also introduces the relatively new ML techniques for game playing and the Evolutionary and Swarm Intelligence algorithms for conducting efficient learning. Finally, it indicates the direction of future research in AI game-playing algorithms and techniques.

BACKGROUND

Playing games intelligently and trying to win against human champions has been a grand challenge for *Artificial Intelligence* from its inception. Chess, in particular, has been referred to as the *Drosophila* of AI. The first study in computer chess was published by Claude Shannon in 1950 (Shanon, 1950). However, the first working AI programs were for playing checkers (Samuel, 1960; Samuel, 1967). In the 1970s and 1980s, computer-games research concentrated on chess and the brute-force search approach (Schaeffer, 2002). The triumph of AI in computer games came in the 1990s when to everyone's surprise AI programs began to defeat the reigning world

DOI: 10.4018/978-1-5225-2255-3.ch013

champions. In 1994, the program CHINOOK won the World Man–Machine Championship (Schaeffer, 1997). Three year later, IBM’S DEEP BLUE defeated the World Chess Champion Garry Kasparov (Hsu, 2002) and LOGISTELLO won against the Othello Champion Takeshi Murakami (Buro, 1997). Finally, in 2011, IBM’s WATSON defeated the world champions in the quiz game of Jeopardy.

The computer games mentioned above, with the exception of Jeopardy, are all two-player board-games. Any classic board-game playing algorithm makes a static list of all possible moves of the two players called the game tree, at a given stage of the game. It then assigns a relative score to each of the position. The algorithmic game playing strategy consists of efficiently searching through the moves that maximize the score. However, in practice, the number of moves even for any modest game are astronomically large and an exhaustive search is impossible. Specialized super-computers like the DEEP BLUE and WATSON greatly improves the depth and breadth of the search, but in no way is it exhaustive. AI techniques deal with the design and implementation of algorithms that provide short-cuts in the search. These AI algorithms also combine the power of Machine Learning to further reduce the search path. The AI techniques and their future development is described in detail in the following sections.

BOARD GAMES

This section describes the characteristics of two-player board games. The two players taking turns in playing give rise to a “turn game”. The unfolding of the game on the board surrounded by the two players can be represented by an abstract graph called the game tree. These two concepts are defined in the following sub-sections.

Turn Games

In the simplest board games, there are usually two players. These are called turn games, because each player takes a turn in playing. The game proceeds by the two players taking turns alternately. The outcome of a two-player turn game is either a win, a loss or a draw for each of the players concerned. The two-player board games are, therefore, zero-sum games – the net outcome score is zero. Let’s say, the score for winning is +10, for losing is -10 and for drawing the game is 0. The zero-sum turn play necessarily implies that a win for a player results in a loss for the opponent and vice versa. The sum of the scores at the end of the game is zero (+10-10). In the case of a draw situation also, the sum is zero.

Perfect information is another underlying assumption in a two-player turn game. It is assumed that the two players have complete knowledge of the progression of the game till the end result. In other words, any of the two players at any given point in the game knows all the possible move options at that point and all the possible outcomes emanating from each of those moves. This is opposed to random games which may involve the rolling of a die in which none of the players can predict the next move because of its intrinsic non-deterministic nature.

Game Tree

The complete information about the progression of the turn game that each player has access to can be represented in a graph consisting of nodes and edges. This graph is called the game tree. The nodes in the graph represent the board positions (configurations), and the edges represent the possible moves a player can choose to make. The starting position of the game is represented by the *root* node. A single move transports the game from the *parent* node to one of the next level *children* node. The end of the game is represented by the *leaf* nodes.

Figure 1. Tic-Tac-Toe game tree

Figure 1 shows the game tree for the Tic-Tac-Toe game. The root node is the starting position of the board without any markings. The player playing 'X' has three possible moves (leaving aside the symmetrical positions of the board). These are shown in the next level of nodes, called the children nodes. The branches connecting the parent nodes and the children nodes represent the moves made by the player. Each level of play is called a ply. Each ply is where the turn switches to the other player. The bottom nodes without any branches are called leaves and signify the end of the game.

MINMAX ALGORITHM

The *MiniMax* algorithm (Plaat, 1997) developed by the AI community, provides a winning strategy in board games with perfect information. It is an intelligent approach to trace a winning path in the game tree given a heuristic or evaluation function that evaluates the goodness of the game position. "Min" and "Max" are the two players taking turns in the game. Max tries to maximize his/her score, while Min tries to minimize Max's score. Hence, the name *MiniMax* (or *MinMax*). The basic assumption is that both the players play an ideal game. While choosing the moves, Max will choose the best move to maximize his/her score while Min will choose the best move to minimize the score of Max.

Figure 2. MiniMax algorithm

Table 1. State-space and game-tree complexity of board games

Game	State-Space Complexity	Game-Tree Complexity	Branching Factor	Average Game Length (Plies)
Tic-Tac-Toe	10^3	10^5	4	9
Connect Four	10^{13}	10^{21}	4	36
Othello	10^{28}	10^{58}	10	58
Checkers	10^{21}	10^{31}	-	-
Chess	10^{46}	10^{123}	35	80
Shogi	10^{71}	10^{226}	92	115
Go	10^{72}	10^{360}	250	150

Let us assume that Max (computer program) has won the toss to begin the play. The *MiniMax* algorithm proceeds through the following steps to determine the optimal winning strategy for *Max*.

1. Generate the entire game tree from the root node to the leaf nodes.
2. Evaluate the score of each leaf node by applying the evaluation function.
3. Back-up values from the leaf nodes through the branch nodes.
 - a. Assign the *maximum* value of the child nodes to the Max node.
 - b. Assign the *minimum* value of the child nodes to the Min node.
4. Terminate the backup procedure at the root node.
5. Follow the (winning) path from the root node to the leaf node traced through steps 1-4.

ALPHA-BETA PRUNNING

The game tree represents all the possible legal moves in the board game and the *MiniMax* algorithm provides an efficient way of searching for the successive winning moves throughout the nodes and branches of the game tree. However, real-life implementation of the *MiniMax* algorithm down to the last leaf nodes of the game tree is impossible. The state-space and game tree complexity, as shown in Table 1 are prohibitively large (Nilsson, 1998; Iida, Sakuta, & Rollason, 2002; Luger,

2005; Russell, & Norvig, 2010; Calero, 2011). This problem is partially solved by applying the evaluation function to a couple of moves ahead and then back-calculating the goodness of the current playing node. Even this look-ahead strategy is computationally expensive. The α - β version of the *MiniMax* algorithm (Pearl, 1982) further reduces the search complexity by effectively cutting off some of the branches of the game tree.

The algorithm maintains two values, α and β , which represent the maximum score that the maximizing player is assured of and the minimum score that the minimizing player is assured of, respectively. Initially α is negative infinity and β is positive infinity, i.e. both players start with their lowest possible score. It can happen that when choosing a certain branch of a certain node the minimum score that the minimizing player is assured of becomes less than the maximum score that the maximizing player is assured of ($\beta \leq \alpha$). If this is the case, the parent node should not choose this node, because it will make the score for the parent node worse. Therefore, the other branches of the node do not have to be explored.

The α and the β values during the search are computed as follows: (Nilsson, 1988; Luger, 2005)

The α value of a *Max* node is set equal to the current largest final backed-up value of its successors.

The β value of a *Min* node is set equal to the current smallest final backed-up value of its successors.

Figure 3. Alpha-Beta pruning

The search is discontinued under the following rules:

- **α Cut-Off Rule:** Search can be discontinued below any *Min* node having a β value less than or equal to the α value of any of its *Max* node ancestors. The final backed-up value of this *Min* node can then be set to its β value.
- **β Cut-Off Rule:** Search can be discontinued below any *Max* node having an α value greater than or equal to the β value of any of its *Min* node ancestors. The final backed-up value of this *Max* node can then be set to its α value.

For example starting at node Q (Figure 3), the algorithm descends in depth-first order and computes the value of the evaluation function for each of the leaf nodes. These values are backed up to the parent node U (Max = 5). This is then assigned to the grandparent node Q, as its β value. It cannot have a value larger than 5. The algorithm then descends to node Q's grandchildren and the search of their grandparent is terminated if any grandchildren is greater than or equal to Q's β . Node V is β pruned as shown in Figure 3. The algorithm continues pruning the tree with α and β cuts till the end of the right branch.

MACHINE LEARNING TECHNIQUES IN BOARD GAMES

Machine Learning and Neural Networks

Machine Learning (Mitchell, 1997; Mohri, & Rostamizadeh, 2012; Salev-Shwartz, & Ben-David, 2014) is an important research area in AI. It deals with three types of learning algorithms – (1) Supervised learning or classification in which a set of input-output data are provided to perform the task of learning or deriving the input-output pattern or mapping in the data; (2) unsupervised learning or clustering in which the algorithm learns to organize the data in clusters based on some entropy or statistical measures, and (3) reinforced learning in which the learning algorithm is given positive accumulative score for every successful performance.

The most common structures for implementing machine learning are Artificial Neural Networks (Anderson, 1995; Picton, 2000; Du, K.-L., Swamy, M. N. S., 2014). An Artificial Neural Network (ANN) consists of several layers, namely: an input layer, a number of hidden layers and an output layer. The input layer and the hidden layer are connected by links called weights and likewise the hidden layer and output layer also have connection weights. When more than one hidden layer

Figure 4. Multilayered neural network

exists, weights exist between such layers. Neural networks use some sort of learning rule by which the connection weights are determined in order to minimize the error between the neural network output and the desired output. In many applications, using only a single hidden layer is common. Each neuron in the hidden layer sums the weighted inputs from the input layer and passes the sum through the non-linear sigmoidal or hyperbolic activation function. A similar processing takes place in the output layer resulting in an output.

Neural Networks in Game Playing

ANN learning consists in adjusting the connection weights. These represent the strength of the synapses among the neurons in the human brain. Learning is conventionally carried out by the Back-Propagation Algorithm (BP) (Abid, Fnaiech, & Najim, 2001; Xinghuo, Efe, & Kaynak, 2002). Recently, Evolutionary Algorithms (Carpentieri, 2009; Gill, Singh, & Singh, 2010; Yorita, & Kubota, 2011,) and Swarm Intelligence algorithms (Van den Bergh, & Engelbrecht, 2000; Selles, & Rylander, 2002; Zhang & Zhang, 2007; Jin, Chang, Cheng, & Jiang, 2011; Gonsalves, & Oguro, 2014;) have also been applied to further improve the BP performance in learning.

ANN are also found to learn and excel in playing games without injecting any expert knowledge about how to play the game (Fogel, 1995). Some studies use neural network evolution through learning to guide the game tree search (Lee, 1990; Moriarty, & Miikkulainen, 1995) while others evolve neural networks to act as evaluation functions for the minimax search (Fogel, 1995; Chellapilla, & Fogel, 1999;). Initially, the connection weights are randomly generated and some relevant information such as the board configuration, the number of pieces on the board, etc. is fed to the input layer of the ANN. The neurons in the ANN layers fire and give an output, which usually indicates the move to be made. Several agents (programs), each driven by an ANN, play against each other till they reach the end of the game. The winning agent is given a reinforcing reward, and the learning cycle is repeated. The learning agent improves its playing strategy with each learning cycle.

For example (refer to Figure 5), in the case of an agent learning to excel at the game of othello, the board configuration, the piece differential and the legal moves from the current position are fed to the input neurons in each learning cycle (Lee, 1990; Chong, Ku, Lim, Tan, & White, 2003). The ANN outputs the move the agent is to play next. The opponent is normally another agent driven

Figure 5. Neural network learning othello wining moves

by expert heuristics or by another ANN. After the response of the opponent, the agent calculates the next move as the output of the ANN. This sequence of actions continues till the end of the game. A large number of games are played to achieve the desired level of expertise. After each game, the connection weights of the ANN are adjusted either by the back propagation algorithm or some optimization algorithm.

FUTURE RESEARCH DIRECTIONS

Evolutionary Algorithms, Neural Networks and Fuzzy systems form the basis of Computational Intelligence – a new version of AI with considerable success in the solution of practical problems. Evolutionary algorithms (EA) and Swarm Intelligence (SI) algorithms are called bio-inspired algorithms since their computational models are inspired by the biological processes and natural phenomena. The Genetic Algorithm (Sivanandam, & Deepa, 2007) and Genetic Programming (Reilly, 2005) are typical EAs directly modelled on the Darwinian natural selection principles, while the Swarm Intelligence algorithms are modelled on the feeding behavior of a swarm of birds or a school of fish (Engelbrecht, 2005). EA and SI

techniques have been primarily applied to solve optimization problems in diverse fields. They are gradually finding their way into the arena of PC board games. For example, they can learn the best playing strategy by efficiently searching through the massive game-tree (Karamchandani, Gandhi, Pawar, & Pawaskar, 2015; Ling & Lam, 2011). These techniques are also hybridized with ANN to produce advanced systems for efficient learning of game-playing strategies (Cant, Churchill, & Al-Dabass, 2002).

Monte Carlo Tree Search (MCTS) is a random sampling tree search method that creates a partial game tree and then searches for the best move based on its simulated gametheoretic value (Browne, Powley, Whitehouse, Lucas, Cowling, Rohlfshagen, Tavener, Perez, & Colton, 2012). MCTS method has been successfully applied to the games of Go (Bouzy, 2006), Ms Pac-Man (Samothrakis, Robles, & Lucas, 2011), and so on. Inexpensive yet powerful hardware and advanced graphics techniques coupled with newer versions of the old AI algorithms (Díez, Laforge, & Saerens, 2003) have contributed to the revival of the two-player board games. Card games which involve an element of chance were not considered in the “intelligent games” categories like chess, othello, go, etc. However, the present-day AI has

begun embracing card games also (Cowling, Ward, & Powley, 2012; Sephton, Cowling, Powley, & Slaven, 2014). This is possible because of the successful machine learning algorithms.

CONCLUSION

This chapter has explored some of the classic AI algorithms for playing board games like tic-tac-toe, checkers, othello, chess, etc. The two-player zero-sum deterministic board games are the classic games to attract the attention of the (early) AI researchers. The playing strategy of the computer program consists in presenting the moves of the two players in the form of a game tree, applying a suitable heuristic evaluation function to the game tree end nodes and backtracking to the current board position in the game. This kind of an ideal search is performed using the *MiniMax* algorithm. However, even in the case of a simple game like Tic-Tac-Toe the number of nodes soon become astronomical with the depth of the game tree, making the exhaustive search impractical and infeasible. The alpha-beta pruning offers an effective way to safely prune the futile branches. A recent AI method in game playing is Machine Learning using Neural Networks. The program learns to master the winning strategy through trial-and-error and at times through supplementing expert knowledge. Some of the latest machine learning algorithms combine the power of Evolutionary Algorithms or Swarm Intelligence with Artificial Neural Networks. Development of Monte Carlos Tree Search and deep-learning techniques hold the future for game-playing AI.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: It is a branch of computer science concerned with making computers do things that require intelligence when done by human beings.

Board Game: It is a game in which two or more players take turns in placing or moving pieces on a pre-marked surface or board, according to a set of rules.

Game Tree: It is a graph consisting of nodes and edges that represent all the possible legal moves of a (board) game. The nodes are positions in a game and the edges are moves.

Machine Learning: Refers to the activity or ability of computer programs to learn without being explicitly programmed given an adequate amount of data.

MiniMax Algorithm: It is a winning search strategy through the nodes and branches of the game tree. It is based on the principal that the algorithm's opponent will try to minimize whatever value the algorithm tries to maximize.

Neural Network: A network consisting of several layers of nodes and connections with weights which models the information processing operation of the human brain. Neural networks are used in Machine Learning as universal function approximators.

Ply: Refers to the number of levels in the game tree including the root level.

Zero-Sum Game: It is a situation in which one player's win implies the other's loss. The sum of the scores in the win-loss or the draw is always zero.

Computational Intelligence Approaches to Computational Aesthetics

INTRODUCTION

Computational aesthetics is an area of research which attempts to develop computational methods that can perform aesthetic judgements in the same way as humans (Hoenig, 2005). It is an area of research which has not developed as a separate discipline till relatively recently. The notion of aesthetics is highly intuitive and often subjective. An aesthetic experience can be negative, positive or more subtly nuanced. Human beings have a strong and deep sense of aesthetics, however rationalising aesthetic decisions is challenging. As such developing computational models to make aesthetic decisions is particularly challenging.

While computational intelligence techniques such as evolutionary algorithms have been able to solve many real world challenges, still such techniques are not widely used to solve problems that involve aesthetic decisions. Making an aesthetic decision often requires a human in the loop which in turn creates a barrier between computational intelligence and aesthetics. However recent advancements in computational aesthetics have made computer generated art and aesthetics realisable in several domains (den Heijer & Eiben, 2012; DiPaola & Gabora, 2009).

The purpose of this article is to summarise the advancements in the area of computational aesthetics, challenges involved, computational intelligence approaches to art and aesthetics and possible future directions. The article first summarises early attempts to define aesthetics,

through to more contemporary definitions and attempts in developing computational models of aesthetics in various domains. Then, it highlights the challenges associated with bridging the gap between aesthetics and computational intelligence. Thereafter it discusses how computational intelligence techniques are used in art and aesthetics ranging from simple classification problems to more advanced problems such as automatic generation of art artefacts, stories and simulations. The article concludes highlighting the future research directions that need to be undertaken in order to make significant advancements in computational aesthetics and its applications.

BACKGROUND

Aesthetics

The study of aesthetics is chiefly a branch of philosophy with links to other disciplines such as psychology. The term aesthetics was derived from the Greek word *aisthanesthai* (to perceive (by the senses or by the mind)) and introduced into the philosophical terminology in the eighteenth century (Saw & Osborne, 1960). The definition of aesthetics is a long standing debate. Early definitions of aesthetics are related to art or beauty (Santayana, 1904). Later attempts to define aesthetics discuss that aesthetics mean more than just art and natural beauty (Walton, 2007), (Palmer, Schloss, & Sammartino, 2013). Therefore more

contemporary definitions are woven around human mental processes involved in making aesthetic judgements; for example:

- *The study of human minds and emotions in relation to the sense of beauty (Palmer et al., 2013).*
- *Psychological mechanisms that allow humans to experience and appreciate a broad variety of objects and phenomena, including utensils, commodities, designs, other people, or nature, in aesthetic terms (beautiful, attractive, ugly, sublime, picturesque, and so on) (Leder & Nadal, 2014).*

Computational Aesthetics

Computational aesthetics is an area of research which attempts to develop computational methods that can perform aesthetic judgements in the same way as humans (Hoenig, 2005). Classifying something as aesthetically appealing or not appealing might be relatively easy for a human even though it is subjective; however for a computer it is not straight forward to make such determinations. As such, a considerably large amount of literature attempts to define explicit measures of aesthetics that make it possible to distinguish aesthetically appealing objects from objects that are not.

In 1933, Birkhoff defined an aesthetic measure M , which can be explained as the regularity (order) perceived in an aesthetic object for a unit of effort (complexity) (Birkhoff, 1933). This can be defined as $M = \frac{\text{order}}{\text{complexity}}$. The introduction of this measure is considered as the beginning of computational aesthetics. This measure was investigated by later researchers in relation to information theory. In 2007, Rigau, Feixas, and Sbert (2007) analysed the concepts of order and complexity for pixel values of paintings based on Shannon entropy (Shannon, 1948) and Kolmogorov complexity (Kolmogorov, 1965) and presented a new conceptualisation of Birkhoff's

aesthetic measure based on Zurek's physical entropy (Zurek, 1989). However, vision researchers argue that true entropy of an image, being a perceptual quantity, cannot be characterised with image statistics such as Shannon entropy (Graham & Redies, 2010).

Vision scientists have analysed whether humans have a preference for images that have similar spatial statistical structures to those that the human visual system has adapted for (Palmer et al., 2013). For example, Graham and Field (2007) have identified that paintings (a sample taken from a Museum of Art) and natural scenes have similar Fourier amplitude spectra. Similarly, Spehar, Clifford, Newell, and Taylor (2003) show that humans have a preference for fractal structures irrespective of whether they are natural or man-made.

There is a considerable amount of literature that discuss the shape of an object as an aesthetic measure. Several researchers have reviewed Golden Ratio/Golden Section as an aesthetic measure in various fields (Benjafeld, 1976; Gilmartin, 1983; Green, 1995; McManus, 1980; Russell, 2000). If a line is divided into x : $(1-x)$ ratio, the Golden Ratio arises when $1/x = x/(1-x)$ (Markowsky, 1992). This value is denoted by F and $F \approx 1.618$. However, the results in the field are controversial and some studies have shown that the Golden Ratio have no special aesthetic appeal (Boselie, 1984; Davis & Jahnke, 1991; Markowsky, 1992).

Some studies have discussed the symmetry of an object as an aesthetic factor (Locher & Nodine, 1989; Osborne, 1986). Several recent such studies have shown that people have greater preference towards curved objects than objects with sharp contours (Bar & Neta, 2006; Silvia & Barona, 2009). However these measures are fragile and susceptible to many other factors depending on the domain of interest so that their applicability as an aesthetic measure is limited.

Although there is a huge amount of literature on attempts to measure aesthetics in various disciplines, currently there is no universal measure

of aesthetics. However, these various proposed aesthetic measures provide the basis for developing computational methods of aesthetics, enabling computational aesthetics to develop as a discipline.

In particular, computational aesthetic techniques can currently be used to make aesthetic decisions primarily in two different ways as follows.

- Aesthetic Classification.
- Aesthetic Scoring.

Aesthetic Classification

Categorising objects, situations or phenomena into several classes based on their aesthetic quality can be treated as an aesthetic classification problem. Several works attempt to automate human aesthetic judgement for classification problems by training a machine learning system. In particular these works demonstrate promising results of applying computational aesthetics techniques to train machine learning classifiers in order to predict aesthetic ratings or other subjective judgements such as interestingness of photographs (Datta, Joshi, Li, & Wang, 2006; Dhar, Ordonez, & Berg, 2011, paintings (Li & Chen, 2009) and consumer videos (Moorthy, Obrador, & Oliver, 2010).

Aesthetic Scoring

Rating objects, situations or phenomena for their aesthetic quality in a discrete or a continuous range can be treated as an aesthetic scoring problem. Similar to classification problems there are attempts to automate aesthetic scoring through machine learning approaches in several problem areas such as digital portraits (Battiato, Moltisanti, Ravi, Bruna, & Naccari, 2013) computer generated stories (Wang, Bui, Petraki, & Abbass, 2012) and computer simulation of emergent behaviours (Lakshika, Barlow, & Easton, 2012). Apart from aesthetic feature extraction, one of the primary challenges in both aesthetic classification and scoring problems is finding labelled training data.

Computational Intelligence

Computational intelligence is a branch of artificial intelligence which is aimed at developing systems that can demonstrate intelligent behaviour in complex and changing environments based on adaptive methods and algorithms that are able to learn new situations, generalise, abstract and associate (Engelbrecht, 2007; Kruse et al., 2013). Often computational intelligence techniques apply nature-inspired approaches to find approximate solutions to problems that are difficult to solve using traditional methods. However, being nature-inspired is not a necessary trait for a technique to be categorised as computational intelligence.

Computational intelligence techniques have been able to solve many challenging real world problems including classification, planning, decision making and optimisation in a range of application areas such as engineering, economics, defence and medicine. However, when it comes to problems that involve aesthetic decisions, computational intelligence techniques are still not widely used as compared to the other problem areas.

Aesthetics are involved in many aspects of everyday life, and people make aesthetic decisions consciously or subconsciously. In the contemporary society where automation has become a major part of people's lives, making computers more aesthetic-aware has become a need so that the decisions assisted by the computers (e.g: designing a city, designing a computer game) match with human aesthetic preferences. This is where integrating computational intelligence techniques and aesthetics becomes particularly important.

COMPUTATIONAL INTELLIGENCE APPROACHES TO COMPUTATIONAL AESTHETICS

The recent re-emergence of the term computational aesthetics is related to computational intelligence, especially in relation to evolutionary art and music

(Greenfield, 2005). Evolutionary computation is a computational intelligence technique inspired by the evolution of biological species in nature and utilises the underlying abstract concepts of Darwinian evolution: natural selection and survival of the fittest to perform a stochastic search for solutions to a problem. A detailed introduction to evolutionary computing can be found in (Eiben & Smith, 2003). According to Darwinian principles, in nature, evolution occurs by combining the genes of parents to produce a new offspring (recombination). During this reproduction process small random variations (mutations) occur and new traits are produced. These new individuals are evaluated for environmental conditions based on an objective function (fitness evaluation). As per the concept of natural selection, those individuals who adapt to the environment conditions best, have a better chance of survival (i.e: the concept of survival of the fittest). According to this process, the individuals with higher fitness have more chance to reproduce than those with a lower fitness and favourable traits are passed to the offspring. Through mutations, new traits are also introduced. Therefore, as this process iteratively continues, the populations evolve towards better quality individuals. Evolutionary algorithms mimic this process in order to search for/create better solutions.

Evolutionary art and aesthetics focus on using evolutionary computing techniques such as natural selection and survival of the fittest in order to automatically generate art and aesthetics. For an evolutionary algorithm to automatically generate art and aesthetics a well-formulated objective function is required. Due to the inherent subjective nature of aesthetics judgements, defining an appropriate objective function is extremely challenging for aesthetic related applications.

Interactive evolutionary algorithms have been introduced to overcome this challenge by having a human in the loop providing aesthetic judgements. An interactive evolutionary algorithm works similarly to any other standard evolutionary algorithm with the exception of having the

interaction of human/humans to determine the fitness of the solutions. Interactive evolutionary techniques have been employed to evolve many systems that involve creativity and aesthetics such as music (Tokui & Iba, 2000), paintings (Aupetit, Bordeau, Monmarché, Slimane, & Venturini, 2003), graphics (McCormack, 1993; Sims, 1991) and various design problems (Kim & Cho, 2000; Oliver, Monmarché, & Venturini, 2002). Further, Chen, Kobayashi, Kawabayashi, and Huang (2008) have employed an interactive genetic algorithm to optimise the coefficients (weights) of an extended boid model (Reynolds, 1987) to simulate fish schooling behaviour. Karl Sims' work (Sims, 1991) is one of the notable examples of evolutionary arts and aesthetics. This work used an expression-based approach to evolve images using an interactive selection mechanism, demonstrating the feasibility of automatic generation of beautiful and complex images using such approaches. This inspired many artists and graphics programmers to apply similar techniques for automatic image generation and substantial bodies of work have been done to date.

One of the common problems in an interactive evolutionary system is user fatigue (Takagi, 2001). Users become inconsistent over time and consequently, evolutionary population size needs to be kept low. While some authors (Draves, 2005) have employed crowdsourcing to address user fatigue, there is a trend of seeking automated (non-interactive) mechanisms to determine human aesthetic judgement through computational aesthetic techniques.

The work by den Heijer and Eiben (2010) analyses three aesthetics measures based on Benford Law, Global contrast factor, and Information theory to evolve art. The three aesthetics measures have generated different styles of images and cross-evaluation of each aesthetics measure on the other two measures confirmed that no measure appears to appreciate the images generated by the other measures. den Heijer and Eiben (2012) present some early results in evolving pop art using colour contrast as an objective function for

a Scalable Vector Graphics (SVG) based genetic programming system. DiPaola and Gabora (2009) demonstrate the evolution of abstract portraits through a genetic programming based approach utilising an automated fitness function based on resemblance, composition, tonality and colour rules. However, it would be interesting to see a cross evaluation of these evolutionary art and paintings with artists or humans.

Baluja, Pomerleau, and Jochem (1994) present an early attempt to automate human judgement on the aesthetics of images through training a neural network with the intent of using that as an objective function to an evolutionary algorithm. The approach uses the two-dimensional pixels of an image as input to the neural network and human rating for them to train the network. The results showed that the automated system can prune out the bad images; however the performance on good images was not as accurate. This is due to the lack of good images in the training set, which they collected through several interactive evolutions. However, this research opened up some interesting research directions in automating human judgement.

Machado, Romero, and Manaris (2008) co-evolved the classifier and the evolutionary system in order to explore the images that are classified as paintings by the neural network. The system generated images are assumed to have a low aesthetics value and external images (a set of famous paintings) are assumed to have a high aesthetics value. The neural network was trained iteratively by inputting the solutions found during the evolution to the training set. This overcomes the limitation of lack of training images in the training set; however, the work does not address the challenge of completely automating human aesthetic judgement.

More recent work by Wang et al. (2012) attempts to define an approximated human story evaluation model in order to objectively evaluate the quality of computer generated stories. This work presents correlations between several objective metrics and subjective human evaluations so

that the objective metrics can be used as surrogates for human evaluations and be used as an objective function for an evolutionary algorithm. Lakshika et al. (2012) show that human judgement of aesthetic quality of standing group conversation behaviour simulations can be recreated by a machine learning system. In this work, the features used by humans to make aesthetic judgements are used to extract features from the simulations and such features were input to the sequential minimal-optimisation algorithm for learning a support vector regression model (Smola, & Schölkopf, 2004). In this work, leave-one-out cross validation results of the trained machine learning system showed a correlation co-efficient of 0.88 (in a range of 0-1, higher the co-efficient better the result) between the human scores and the machine generated scores; and a root mean squared error of 0.86 (in a range of 0-9, lower the error better the result). This machine learning system was then utilised to automatically generate high fidelity (aesthetically appealing) conversational group dynamics simulations via an evolutionary system. The work not only shows the ability of a machine learning system to capture human aesthetic judgement, but also the ability of a computational intelligence approach to generate aesthetically appealing crowd simulations. Later work by Lakshika, Barlow, and Easton (2016) explores a relationship between simulation model complexity and simulation fidelity in multi-agent systems by employing this framework in three problem domains, namely conversational group dynamics simulations, sheepdog herding simulations, and lane merge traffics simulations showing that the approach can be extended to automatically generate high fidelity multi-agent simulations.

FUTURE RESEARCH DIRECTIONS

While the field of computational aesthetics has made significant advancements over the recent decades, one of the limitations of the field is lack of validations. Current studies are limited to specific problems with limited cross evaluations;

hence large scale validations of computational aesthetic models are essential for their wider use in the tasks that traditionally require humans in the loop. This is particularly difficult as aesthetic decisions can reflect the opinion of a person, a group of people or multiple groups of people with varying demographics. While developing universal models of computational aesthetics is extremely challenging, research is required towards developing computational models of aesthetics that can adapt to various user groups and changing circumstances.

It is likely that merging computational aesthetic techniques with other complementary research techniques used in such areas as affective computing (Picard, 2003) and sentiment analysis (Liu, 2012) will greatly be beneficial to the field. This will also be useful to deal with the inherent philosophical and methodological issues arising from the subjective nature of aesthetics.

CONCLUSION

Computational aesthetics techniques have made significant advances over recent decades. These advances together with computational intelligence techniques have made computer generated art and aesthetics realisable in a number of targeted application areas. If these advancements continue, significant positive impacts on the areas that traditionally require a human in the loop to provide creative and aesthetic judgements are inevitable. The aim should not be to replace humans with a computer but to achieve more creative and novel outcomes by humans and computers working together complementing each other's skills.

KEY TERMS AND DEFINITIONS

Aesthetic Classification: Categorising objects, situations or phenomena into several aesthetic classes based on their quality.

Aesthetic Scoring: Rating objects, situations or phenomena for their aesthetic quality in a discrete or a continuous range.

Aesthetics: Study of human mental processes involved in appreciating a subjective experience and its quality in a wide variety of objects, situations and phenomena. An aesthetic experience can be positive, negative or more subtly nuanced.

Computational Aesthetics: An area of research focused on developing computational models and techniques that are capable of making human-like aesthetic decisions.

Computational Intelligence: The application and development of adaptive computational techniques focused on making systems that can demonstrate intelligent behaviour in complex and changing environments.

Evolutionary Art: An area of research focused on utilising evolutionary computing techniques to automatically create art.

Evolutionary Computing: A computational intelligence technique inspired by the evolution of biological species in nature and utilise the underlying abstract concepts of Darwinian evolution: natural selection and survival of the fittest to perform a stochastic search for solutions to a problem.

INTRODUCTION

The new era has heralded several developments in technology; technological determinism has improved as well as complicated the human life. Among several challenges encountered by society security ranks as the first and foremost in present world. Every nation is facing the nuisance and security threat one way or another, from criminal activities to group initiated terrorism indiscipline is reigning supreme from Asia to Americas. In such a world providing security is of utmost significance. In this regard knowledge-based or token-based security systems are well suited to protect a system. To date several systems are implemented that use the conventional method of User ID and Password for protection. Few examples include On-line banking, E-mail system and ATM etc. the issue associated with such systems is that they can fail in advent of hacking or stolen card. Fraudulent users can easily predict short length passwords. If we encourage the user to implement long passwords then memorization becomes a daunting task. Such systems are considered as insecure therefore are less recommended. We can identify any person in several ways Signatures, Identity card, retinal recognition, voice recognition, hand geometry and face recognition techniques. A lot of work is being done in biometric technology. Through biometrics unique characteristics of a human being can be

recognized. Biometric covers physiological (direct measurement of any part of human body, finger scan, body scan, facial recognition, retina, hand scan etc) as well as behavioral (based on direct measurements derived from an action, voice scan, signature scan, gait characteristics, project hostile intent are the common examples as described in Figure 1.

Face recognition has proven itself during the past few years. It is considered as most significant application of image analysis. There might be two reasons for this trend one is its broad spectrum application in law enforcement and commercial applications and second could be the potential of this technology to play a pivotal role in near future. The concept of human face recognition using machines poses a challenge that attracts researchers from several disciplines like neural networks, computer vision, and computer graphics image processing and pattern recognition. Most face recognition systems are not excellent when it comes to reliability of identification like using cosmetic operation and face mask. All these systems have significance due to following reasons: all the biometric systems require some action on part of the user for example, user placing hand on finger recognition machine, one also has to stand firm or in anatomical position to be captured correctly by the camera for retina recognition. However, face should be picked up from a distance irrespective

DOI: 10.4018/978-1-5225-2255-3.ch015

Figure 1. Biometric system

of specific position. The algorithm can recognize face using partial facial features extracted from poorly captured photographs; this procedure is for surveillance and security projects. There are other shortcomings to biometric systems this includes damage to the epidermis tissue in case of hand and finger recognition (like bruise or any other abrasion's). Iris and retina recognition requires expensive setup and is dependent on the movement of the face. The voice recognition is vulnerable to background noise, fluctuations in phone line and tape recordings. If we talk about signatures they can be copied or forged so we need to focus on how to detect the pressure exerted on the pen while producing the signatures. In contrast to all these techniques face recognition is possible using couple of in expensive camera and in a fixed position. Efficient recognition algorithm can compensate for noise, scale and illumination. Face recognition is now a very demanding area in research, in this process the captured face is compared with known face image in the database, identification is a tedious task because of light conditions, pose, ageing factor and capture quality, this is an active field of research with focus on generating accurate and better result with fast processing time in fields like human computer interaction and biometrics (Gaidhane, Hote, & Singh, 2014).

Finally, the other technologies mentioned induces the vulnerability to germs and impurities due to the physical contact of different users with

the device, the most beautiful aspect of face recognition is that since it is stereo-photogrammetric technique it is non-destructive, non-intrusive and non-contact and hence reduces the chances of health risk substantially (Jafri & Arabnia, 2009). Such a technique can be easily incorporated by the engineers while constructing security system since their National Society of professional Engineers (NSPE) Code of ethics advocates this practice in their fundamental canon:

An Engineer should hold paramount the safety, health and welfare of the public.

BACKGROUND

As discussed face recognition approaches are one of the most attractive research areas for the researchers. A variety of face recognition techniques and methods have been discussed. This technique having no health risks and its social acceptability is high. Face recognition techniques can be categorized in three different methodologies — holistic, feature and hybrid. A holistic method is based on the global feature information of human face. Its accuracy rate is always high as this technique is built on the core features of human face. Feature based method is a structure matching technique. In this method eyes, nose and lips are considered for structural pattern matching to identified human faces. A hybrid method is a combination of holis-

Table 1.

S. No	Face Recognition Method	Description
1.	Structural Matching	In this method the face recognition is based on linear distances between key features of human face (Cox <i>et al.</i> , 1996).
2.	Principal Component Analysis (PCA)	PCA method used Eigen-picture coordinate space to demonstrate facial images as described by (Sirovich & Kirby, 1987). This technique also used to re-construct facial structures by using a small collection of Eigen-pictures.
3.	Fisher Faces	Fisher-faces used discriminatory extracted features for face representation.
4.	Independent Component Analysis (ICA)	ICA is a generalization form of PCA, but in situation of ICA the input files are de-correlated by means of second-order statistics
5.	Linear Discriminant Analysis (LDA) / Fisher Linear Discriminant (FLD)	Both LDA and FLD used global features of human faces for the purpose of identification.
6.	Feature Based Approach	This approach based on local key features of human face. The geometry described in this method is based on the locations of human eyes, mouth and nose (Manjunath, Chellappa and Malsburg, 1992).
7.	Hidden Markov Model (HMM)	HMM method based on certain statistical models, which are employed to describe statistical properties of signal.
8.	Hybrid Approach	This method combines both the local and global approaches together. For example in some described face recognition methods global information of human face combined with the local information for the purpose of face identification (Zhao, Chellappa, Phillips & Rosenfeld, 2003).

tic and feature based techniques. The technique, which is discussed in this chapter, is related with feature based method.

Face Recognition Techniques: Literature Survey

For the period last of 3-decades many face recognition methods have been advocated. It is one of the more exciting and stimulating area of research these days. During this period many techniques and methodologies have been introduced to recognized human faces. The earlier techniques were based on the structure of human faces. Relation between distances of eyes, nose and lips were the key parameters to identify human faces (Kelly, 1970). Some techniques used distances and the angles between eyes, mouth, nose, and chin top of human face (Kanade, 1973). Following is the brief description of some face recognition methods, which helps to understand this domain in a more convenient way.

3-D IMAGING TECHNIQUES

Stereo-Photogrammetry Technique

In stereo-photogrammetry the image is captured using two cameras and the obtained results are then overlapped for analysis as given in Figure 2. It can be termed as a singular process mapping 3D object space to 2D image spaces; this concept is of dimensional reduction. Height and curvature (3D) information can be represented on a monitor or on a paper (2D surface) by using standard-light projection.

By replacing one of the cameras with raster slide being projected on human face via multimedia projector as mentioned in Figure 3, we can record the distortions and process them to acquire vital curvatures, in the route altering the passive scanning (stereophotogrammetry) to active-scanning (rasterstereography).

Figure 2. Stereophotogrammetry setup

Moiré Fringe Topography Technique

Moiré fringe topography is utilized for the purpose of height-mapping, having curve like contours of constant distance from the projected screen (Kamal, 1998). Height maps produced by these contours can be epitomized as vectors that are normal to the image plane, it should be noted that the extent of all vectors are relational to the elevation coordinate at the same point. Moiré technique is applied in detection (Kamal, 1998), quantification (Kamal, 1996), documentation (Kamal, 1982) and the track of trunk irregularities in scoliosis position and gait analysis.

Ansari used a custom design wedge calibrated shadow type moiré frame (Ansari, 2008), Further on he studied the precision and accuracy of moiré-fringe-topography setup in the Laboratory. The model of precision and accuracy (Naseeruddin, Kamal, & Firdous, 1998) were changed and tested for moiré system. Height map's quantification was more than 99% precise and accurate. The formulae are defined in (Kamal, 2009) that are used to compute precision and accuracy. Body height maps can be determined using moiré technique.

Figure 3. Conventional Line raster-stereography setup

Shadow Type Moiré Technique

The fringes which we utilized for this experiment is Moiré topology; it is a wooden structure which is lightweight (Akram, 1989). We used fishing line to prepare the grid the only problem with such a structure is that the grid involved pressurizes the wooden frame and there is always a chance of damage being inflicted to the frame, to avoid such a scenario we introduce reinforcements. The method is a good way of recording information and variations the only irony is that the setup requires space.

Grid Projection Type Moiré Technique

This is the type that projects grid on the human face; as a result a changed image is formed corresponding to face shape. This image is then, superimposed on a standard to produce contour line.

The fringes are visible in real time to the human eye, in the shadow as well as the projection type. Where perpetual record in the format of a photo is not a requirement we can setup these images, the drawback is that in case of miss-positioning it cannot be averted in both the cases once the picture is recorded.

Grating Hologram Type Moiré Technique

The problem of miss-positioning during recording discussed in the previous section can be removed by using Grating hologram type moiré fringe topography, since it can adjust the moiré fringes after recording. After projecting moiré grid on the human face, the distorted grid is photographed. In order to generate moiré fringes the grid is again projected with the same magnification and angle on the photograph of the distorted grid. For gait analysis, raster recording and moiré the most appropriate type is Grating hologram.

CONVENTIONAL LINE RASTERSTEREOGRAPHY TECHNIQUE

The conventional Rasterstereography is based on a grid, which is constructed on the basis of horizontal and vertical lines as given in Figure 4. Raster stereography is chiefly, a procedure, which can define local curvatures. A camera is switched by a light-propagating system, which projects a square grid on the surface of a subject. The grid can be bred by intervallic extension of rudimentary squares in horizontal and vertical guidelines. The periodic square on projection upon the subject becomes an almost-periodic square. Distorted raster represents the topological properties of subject, conceivably revealing metric of surface. One of the beneficial aspects of the technique is that it does not need a definite prearrangement of apparatus to acquire significant raster, whereas defined geometry limits the moiré format.

Figure 4. Conventional line raster grid

SIMULTANEOUS MOIRÉ AND RASTER RECORDING TECHNIQUE

Concurrent raster and moiré recordings can be executed using a Camera, two audiovisual aid projectors; a moiré grid that is red along with a raster grid that is blue in color are required as given in Figure 5. Both are in chorus, transformed on the face. Matching-red filter is placed, for a color photograph of face which makes the red-moiré grid obscure and the blue-raster grid give the impression of black. The grids were then analyzed using raster stereography algorithms. Now a matching-blue filter was positioned on the image. The raster grid was curbed and the moiré grid appeared black. Later, a typical moiré grid was projected with the same magnification and angle as the distorted grid, to produce moiré fringes. Triumph of this process depended, critically, on correct matching of the colors, which could be upgraded by decreasing bandwidth of the color that grid is utilizing and the matching filters consumed (Kamal, 1996). In recent times, three dimensional bone scanning was anticipated by using coinciding raster and moiré recording, joint with backscatter-X-ray expertise.

Figure 5. Layout for simultaneous moiré and raster setup

PROBLEMS ASSOCIATED WITH LINE RASTERSTEREOGRAPHY

At the initial stages, conventional raster grid, based on stacked-line squares were used to find the curvatures of the surface of a subject. There are many applications in which conventional rasterstereography were used and all the applications were related to the medical domain. Some very common and popular applications of rasterstereography technique are to find spinal deformity in human body (Zuberi, 2002), to analyze back shape of human body (Hackenberg, Hierholzer, Pötzl, Götze, & Liljenqvist, 2003) and to detect trunk deformity in human body and to find the reproducibility of the technique (Mohokum, Mendoza, Wolf, Sitter, Jürgen, & Skwara, 2010). In all these old applications it was very difficult to find the valid curvatures patterns of human body without breaking the lines. The concept of raster-stereography for human face recognition was introduced in 2008 (Kamal, 2008), which was implemented by the first author of this chapter in 2013 (Wasim, 2013). In the experimental setup a conventional raster-grid was projected on human

frontal face. As human face is a curved surface, raster grid were distorted. This distorted grid provided the curvature information of human face as given in Figure 6. For this testing purpose dark black and white line grids were used to record the facial curvatures of human face. As human face having more curvatures as compare to body so during test runs it was observed that a problem of contrast of grid and the skin color of human face (highly curved surface) has generated, especially in gray scale images. Because of this problem of poor contrast, the curved line breaks during extraction using MATLAB code. Hence it was not easy to trace valid line to define curvature information of human face.

Two algorithms were constructed and used to extract valid curvature patterns of human faces:

1. Valid Curve Detection Algorithm (VCDA).
2. Line Traversal Algorithm (LTA).

Valid Curve Detection Algorithm (VCDA)

To set the criteria of valid line the facial image first cropped by an order of 10×13 based on co-ordinate values of cross over points of horizontal and vertical lines. This covered the core features (eyes, nose and lips area) of all recorded human faces. A line treated as valid if it contained ten consecutive coordinate values in a row which

Figure 6. Un-wanted breaks due to grid and skin contrast

obeyed the criteria of valid line detection. Following steps were followed to detect valid line.

- Step 1:** Filtering the anomalies from the captured image
- Step 2:** Check curve validity — ten consecutive cross over points in a row without breaking the line
- Step 3:** Find valid curve in cropped image by pattern matching of valid criteria
- Step 4:** Find the coordinate values of each cross over points in term of (x, y)
- Step 5:** Apply mathematical model and solved decision parameters
- Step 6:** Used these parameters for the purpose of face identification

Problem Encountered

A problem was reported during the valid curve detection. According to the set criteria in VCDA if ten consecutive white pixels were correctly detected without breaking of line then it should be considered as a valid curve. This experimental value of ten consecutive white pixels was set through trial-and-error to run the algorithm onto 400 images. Due to un-wanted breaks in curve the algorithm could not pick all the valid points from the captured image. Figure 7 showed the small breaks in curves, which created huge problem to detect valid curve pattern of human face.

Figure 7. Un-wanted breaks in curve

Line Traversal Algorithm (LTA)

Working of LTA was based on the execution of VCDA. Traversal of each detected line was started during the execution of VCDA. White pixels were followed and turned into gray to show traversal until connection broke as given in Figure 8. If a line was traversed successfully, cross over points were easily detected and coordinate values of each point were found and recorded in to system database. However, the algorithm did not perform accurately, when there were breaks in line resulting in white regions generated. So it was concluded that if both the algorithms executed successfully valid curvature patterns were recorded.

DOTTED RASTERSTEREOGRAPHY TECHNIQUE

Due to the issues related to VCDA and LTA in conventional Rasterstereography technique it was difficult to analyze human facial curvature patterns for the purpose of face identification. A modified raster-stereography concept was introduced. In this technique the raster grid consisted of dots, instead of conventional horizontal and vertical lines are used as given in Figure 9.

This new designed dotted grid minimized the noise effect and coordinates of dots easily extracted. The issues related to conventional raster grid were resolved and valid curved patterns of human face were extracted in a more proper and accurate manner. Set up Specifications of setup are given in Figure 10.

The efficiency of dotted raster to detect all crossover points was increased by reducing the processing time as compare to conventional raster-stereography technique. Dotted raster-stereography technique minimized code complexity and improves efficiency of the system. This modification made the algorithm simple and easy. Pixel and coordinate values of each point were extracted using MATLAB code.

Figure 9. Dotted raster grid

DOTTED RASTER-STEREOGRAPHY TECHNIQUE IN FACE IDENTIFICATION

The dotted-raster-stereography setup was established in “Image Processing Research Lab (IPRL)” at Usman Institute of Technology. The set up consist of a multimedia projector to project the dotted raster grid on human face, a dotted-raster grid (with 0.6 mm inter-dot spacing) contains white dots with black background and an advanced-digital camera to capture the human face and

Figure 10. Dotted raster-stereography setup

distorted grid pattern on human face. The grid consist of dots was projected using multimedia projector on human face. Grid was distorted and was recorded using digital camera and stored in the system database for further processing. The concept is given in Figure 11.

Figure 11. Dotted raster grid projection on human face

PHASES OF FACE-RECOGNITION SYSTEM USING DOTTED GRID

The dotted raster-stereography based face recognition system is divided into three different phases called registration phase, identification phase and verification phase (Chan, 2008). A person face was first register in to system database. At later stage of the system, the register face identified based on calculated decision parameters. In the final phase of the system human face was verified based on exact match of decision parameters from the system database (Attar & Atani, 2012).

Registration

Registration is the first phase of the dotted raster-stereography based face recognition system. In

this phase of the system a human face first capture using a digital camera and stored in the system database for the purpose of verification. The dotted grid projected using multimedia projector on the human face. The grid was distorted as human face having curved surface. These distortions in grid provide the facial curvature pattern of human face. Using mathematical model decision parameters were solved on the basis of coordinate values of distorted points. Each image was assigned a specific ID for authentication purpose. Featured template of the subject was constructed on the basis of two decision parameters mean (M) and gaussian (G) curvatures. Figure 12 showed the working of registration phase.

Identification

This is second phase of the system. In this module a facial featured template of human face was compared with all available templates from the system database to find the best match. If match found that person face basis of facial featured template will be identified. So it is important that before identification phase each person face should be registered in the system database for the purpose of identification. The identification phase needs 1-t-mano comparison to find exact match from the system database (Chan, 2008). Figure 13 showed the working of identification phase.

Figure 12. Registration phase

Figure 13. Identification phase

Verification

Verification phase is the third phase of the system. It is an optional phase and only used when featured template values of two different faces are much closed and it is difficult to identify true face from the system database. So for the purpose of verification there should be a secondary system connected with the main application just to verify and recognized true face. This secondary system may be a ID card number matching system, thumb, iris, retina or voice pattern recognition system. Figure 14 showed the working of proposed verification phase.

RESULTS AND DISCUSSIONS

Figure 15, talk about the five initial sample human faces from the system database. These cases having the reference ID as: IPRL-UIT-2016061-01, IPRL-UIT-2016061-02, IPRL-UIT-2016061-03, IPRL-UIT-2016061-04 and IPRL-UIT-2016061-05. The decision parameters mean (M) and gaussian (G) are different with different faces depend upon the facial curvatures of face. These parameters are the main source of face identification. The dotted raster-stereography technique tested on 800 different human faces (both male and female, age range 16-20 years and an accuracy of 95% were obtained.

Figure 14. Verification phase

Figure 15. Results of sample faces from the system database

S. No	Face ID	Sample Faces	Rasterstereography Technique	
			Mean (M) cm^{-1}	Gaussian (G) cm^{-1}
1	IPRL-UIT-2016061-01		12.0200	24.1200
2	IPRL-UIT-2016061-02		5.1145	13.4530
3	IPRL-UIT-2016061-03		13.0500	33.9976
4	IPRL-UIT-2016061-04		18.4523	41.5641
5	IPRL-UIT-2016061-05		19.9876	52.1110

To obtained best results a registered face tested five times in Image Processing Research Lab. An average value of each individual is reported in Figure 15. The range of five repeated M and G values are discussed as follows:

- The absolute mean and gaussian curvatures of facial image IPRL-UIT-2016061-01 is found to be as $11.9900\text{ }cm^{-1} \leq M \leq 12.09\text{ }cm^{-1}$ and $24.1100\text{ }cm^{-1} \leq G \leq 24.1411\text{ }cm^{-1}$. An average value of mean and gaussian of same face is defined as $12.0200\text{ }cm^{-1}$ and $24.1200\text{ }cm^{-1}$.

- The absolute mean and gaussian curvatures of facial image IPRL-UIT-2016061-02 is found to be as $5.1010\text{ }cm^{-1} \leq M \leq 5.1600\text{ }cm^{-1}$ and $13.3701\text{ }cm^{-1} \leq G \leq 13.4711\text{ }cm^{-1}$. An average value of mean and gaussian of same face is defined as $5.1145\text{ }cm^{-1}$ and $13.4530\text{ }cm^{-1}$.
- The absolute mean and gaussian curvatures of facial image IPRL-UIT-2016061-03 is found to be as $12.9901\text{ }cm^{-1} \leq M \leq 13.0900\text{ }cm^{-1}$ and $33.9802\text{ }cm^{-1} \leq G \leq 33.9999\text{ }cm^{-1}$. An average value of mean and gaussian of same face is defined as $13.0500\text{ }cm^{-1}$ and $33.9976\text{ }cm^{-1}$.
- The absolute mean and gaussian curvatures of facial image IPRL-UIT-2016061-04 is found to be as $18.4411\text{ }cm^{-1} \leq M \leq 18.4610\text{ }cm^{-1}$ and $41.4501\text{ }cm^{-1} \leq G \leq 41.5800\text{ }cm^{-1}$. An average value of mean and gaussian of same face is defined as $18.4523\text{ }cm^{-1}$ and $41.5641\text{ }cm^{-1}$.
- The absolute mean and gaussian curvatures of facial image IPRL-UIT-2016061-05 is found to be as $19.9666\text{ }cm^{-1} \leq M \leq 20.010\text{ }cm^{-1}$ and $52.1000\text{ }cm^{-1} \leq G \leq 52.1600\text{ }cm^{-1}$. An average value of mean and gaussian of same face is defined as $19.9876\text{ }cm^{-1}$ and $52.1110\text{ }cm^{-1}$.

The system identified different faces on the basis of mean and gaussian curvatures. This system can be deployed for the purpose of security based on human face identification. Therefore it is the requirement of the system that all the users' should register first in the system database along with their associated mean and gaussian curvature patterns. Graph in Figure 16 shows the behavior of basic facial curvature patterns of first five sample faces from the system database.

Figure 16. Graphical representations of basic curvatures of sample faces

FUTURE RESEARCH DIRECTIONS

1. By experiments it is now very clear that the dotted raster-stereography method generated better results with more accuracy as compare to conventional raster method. This method now can solve all previous applications, which are based on line grid with less complexity.
2. A circular dotted raster method can be used as moiré fringe topography (MFT) and this can be used in depth analysis and pattern recognition of objects.

CONCLUSION

Dotted raster-stereography has been resolved the issue of un-wanted breaks in curvature patterns, which were reported in conventional raster-stereography technique. It also resolved the issues, related to conventional raster-stereography even when it applied to human body (lesser curved surface). The results of dotted raster-stereography technique are better as compare to conventional

raster technique. It is simple, accurate and easy to extract all the curvature pattern dots without any missing points as it was the main issue with previous technique. So it is now recommended that all previous research work, which are based on conventional raster-stereography technique can be developed using dotted raster-stereography technique to get better results in a more convenient way with high accuracy as well.

KEY TERMS AND DEFINITIONS

A

Conventional Raster-Stereography: This technique used line raster grid to capture facial curvatures of human face.

Dotted Raster-Stereography: This technique used dotted raster grid to capture facial curvatures of human face.

Moiré Technique: It is also a 3-D surface screening technique, which is based on interference of light.

Non-Invasive: Term indicate to safe procedure and no harm during test runs.

Raster-Stereography: It is 3-D surface screening technique.

Stereo-Photogrammetry: Technique, which is constructed on the difference of two images, captured with two different cameras.

Hybrid Computational Intelligence and the Basic Concepts and Recent Advances

Georgios Dounias

University of the Aegean, Greece

INTRODUCTION

In this paper computational intelligence and its major methodologies are introduced in the first place, and then hybrid intelligent systems are defined and the most popular hybrid intelligent approaches are discussed. The increased popularity of hybrid intelligent systems during the last decade, is the result of the extensive success of these systems in a wide range of real-world complex problems, but also has to do with the increased capabilities of computational technology. One of the reasons for this success has to do with the synergy derived by the computational intelligent components, such as machine learning, fuzzy logic, neural networks, genetic algorithms, or other intelligent algorithms and techniques. Each of the partial methodologies provides hybrid systems with complementary reasoning and searching methods that allow the use of domain knowledge and empirical data to solve complex problems. The paper includes recent advances and new findings in the area of hybrid computational intelligence.

BACKGROUND

Computational Intelligence

More than half a century of tentative research has rolled since the term Artificial Intelligence was coined within the members of the computer society, in an attempt to characterize the existence of intelligence nuggets in machine performance and behavior, as well as in algorithmic design and performance. Computational Intelligence represents

the evolution of a part of Artificial Intelligence during the 90's, mostly related to well-established and popular computational techniques, such as neural computation, evolutionary computation, machine learning and fuzzy logic.

According to (Duch, 2007), a brief survey of the scope of CI journals and books including the term computational intelligence in their title shows that at present, it is an umbrella for three core technologies (neural, fuzzy and evolutionary), their applications, and selected fashionable methods.

The IEEE Computational Intelligence Society defines its subjects of interest as neural networks, fuzzy systems and evolutionary computation, including swarm intelligence.

In addition, Professor James Bezdek in (Bezdek, 1994) defined a computationally intelligent system as follows:

A system is computationally intelligent when it deals with only numerical (low level) data, has pattern recognition components, does not use knowledge in the AI sense; and additionally when it (begins to) exhibit (i) computational adaptivity, (ii) computational fault tolerance, (iii) speed approaching human-like turnaround and (iv) error rates that approximate human performance.¹

In the MIT Encyclopaedia of the Cognitive Sciences, the neutral term of computational intelligence is used to gather two complementary views of AI, one as an engineering discipline concerned with the creation of intelligent machines, the other as an empirical science concerned with the computational modelling of human intelligence.

DOI: 10.4018/978-1-5225-2255-3.ch016

According to (Abbot et al, 2002), “either natural systems like brains, immune systems, ecologies, societies or, artificial systems like parallel and distributed computing systems, artificial intelligence systems, artificial neural networks, evolutionary programs, are characterised by apparently complex behaviours that emerge as a result of often non-linear spatio-temporal interactions among a large number of component systems at different levels of organization”.

Consequently, researchers in a number of distinct areas including computer science, artificial intelligence, neural networks, cognitive science, computational economics, mathematics, optimization, complexity theory, control systems, biology, neuroscience, psychology, engineering, etc., have begun to address, through a combination of basic as well as applied techniques, theoretical as well as experimental research, analysis and synthesis of such systems. Intelligent systems could be considered those systems that have the properties of self-maintenance, adaptivity, information preservation, and increase in complexity, but use other means to achieve such objectives.

Computational intelligence tools and techniques have now become methods of choice for a number of complex domains of application, due to their specific characteristics. The area mainly deals with problems related to classification, clustering, optimization and forecasting. For some of the above problem types, computational intelligence could be considered a complementary toolbox to standard Operational Research (OR) methods and techniques for optimization, problem solving and decision-making (i.e., mathematical programming, simulation, probabilistic reasoning, etc.). Some areas of computational intelligence have become particularly known over time, due to their effectiveness in facing specific real-world problems. A very thorough analysis of what is meant by computational intelligence and what the trends of modern AI are can be found in (Nilsson 1998; Chen 2000). Newer publications around the fundamentals of Computational Intelligence as well as related to recent methodological advances and

successful applications have appeared in literature from (Siddique & Adeli, 2013; Kruse et al, 2013; Sztandera 2014; Kacprzyk & Redrycz 2015).

From now on let's consider as main components of computational intelligence, the four main streams of research that dominate the area of AI during the last two decades, namely, (1) fuzzy sets and soft computing, (2) neural networks, (3) genetic algorithms and evolutionary computation (including also nature inspired intelligence) and (4) machine learning² and data mining.

A collection of research work on computational intelligence and learning techniques in the sense presented above can also be found in (Zimmermann et al., 2001; Negoita et al., 2005; Kruse et al., 2013). A reference to the basic concepts of the most popular intelligent components of hybrid intelligent architectures follows.

Fuzzy Logic

Fuzzy logic (Zadeh 1965; Zadeh, 2001), in fact can be seen as a language with syntax and local semantics where we can imprint any qualitative knowledge about the problem to be solved, usually with the assistance of a field expert. The strong point of fuzzy logic is the robustness of its interpolative reasoning mechanism. The impact of Fuzzy Logic has been extremely high during the past years with the appearance of several patents³ awarded all over the world, e.g.

- Number of fuzzy-logic-related patents issued and applied in Japan: 7,149.
- Number of fuzzy-logic-related patents issued in the United States: 21,878.
- Number of fuzzy-logic-related patents applied in the United States: 22,272.
- Fuzzy-logic-related patents issued and applied in WIPO (International): 50,999.
- Number of fuzzy-logic-related patents issued and applied in China: 25,454 (not including all the years, and not including Taiwan or Hong Kong).

- Number of fuzzy-logic-related patents issued and applied in EPO (EU): 3,268 (not including individual countries in Europe).
- Number of fuzzy-logic-related patents issued and applied in Australia: 2,350.
- Number of fuzzy-logic-related patents issued and applied in Canada: 556.

Although fuzzy logic is now a well-established domain, recent editions can be still found in fuzzy logic and its applications like (Singhai, 2013; Trillas & Eciolata, 2015) and also (Jantzen, 2013) in fuzzy control foundations and (Tamir et al., 2015) performing a flashback in the 50 years anniversary of fuzzy logic.

Machine Learning and Data Mining

Machine Learning (Michalski et al 1983; Michalski et al 1986; Mitchell 1997), was conceived four decades ago for the development of computational methods that could implement various forms of learning, in particular mechanisms capable of inducing knowledge from examples or data (Kubat et al., 1997, p.3). Knowledge induction seems particularly desirable -especially from field experts who want to understand the outcome of computational approaches - in problems that lack algorithmic solutions, are ill-defined, or only informally stated. Research in machine learning has been mainly devoted to developing effective methods for building learning (rule-based) systems that will acquire high-level concepts and/or problem solving strategies through examples in a way analogical to human learning. Recent advances in machine learning include implementations in new programming environments and languages like R and Python (Lantz 2013; Grus 2015; Raschka 2015), predictive modelling and data analytics (Flach 2012; Kelleher et al, 2015), future attempts for automated knowledge discovery (Domingos, 2015) and useful tips for developers and technical professionals when they dig deep into data performing one of the modern trends in machine learning research, as that of deep data mining (Bell, 2014).

Evolutionary Computation and Nature Inspired Intelligence

Genetic algorithms (Holland, 1975) provide a way to perform randomized global search in a solution space. Usually a population of candidate solutions, encoded internally as chromosomes, is evaluated by a fitness function in terms of its accuracy. The best chromosomes are combined and reproduced in subsequent generations. Genetic programming, proposed by (Koza, 1992) is an extension to the original concept of genetic algorithms. The population in genetic programming is composed by variable length tree-like candidate solutions. Each of these individual candidates, called program, may have functional nodes, enabling the solution to perform arbitrarily large actions. The idea of evolutionary computation, taken from Darwinian evolution principles, seems to be very promising, as it is the main way of evolution observed also in nature. Similar to the logic embodied in genetic algorithms and genetic programming, is the so-called nature inspired intelligence cluster of algorithms and methodologies. These methodologies derived from natural living and evolving systems such as ant societies, bee colonies, bird flocks and fish schools, are also evolving over time, and prove particularly effective in finding optimal solutions in hard optimization problems by intelligently exploring the search space. See (NISIS, 2005) for detailed definitions and uses of various nature inspired smart information systems implemented and presented in recent literature.

Recently Simon (2013) and Eiben and Smith (2015) have published books with introduction and fundamentals of evolutionary computing. One of the modern trends in the area is massively parallel evolutionary computation (Tsutsui & Collet 2013), applications of evolutionary computation in gene regulatory networks (Iba & Noman 2016) and in mobile networking applications such as mobile ad hoc networks (MANETs), vehicular networks (VANETs), sensor networks (SNs), and hybrid networks (Dorrnsoro et al., 2014). Similarly advances in nature inspired intelligent systems can be found in (Yang, 2014) including

PSO, ACO, BCO, simulated annealing, cuckoo search, the firefly algorithm, the bat algorithm, the flower algorithm, harmony search, as well as hybrid methods containing NII components. In addition, in (Brownlee, 2012) programming tips are given for nature inspired techniques taken by biological and natural systems, such as the adaptive capabilities of genetic evolution and the acquired immune system, and the foraging behaviors of birds, bees, ants and bacteria.

Neural Networks

Neural networks were introduced by (Rosenblatt 1959) and (Widrow & Hoff, 1960) as computational structures that can be trained to learn by examples. Using a supervised learning algorithm, such as the back-propagation (Werbos, 1974), and a training set that samples the relation between input and output, we can perform fine local optimization. They are usually called black-box architectures as their outcome often remains unexplained in terms of comprehensibility, but they are extremely strong generalization mechanisms over data collections. Recent advances in neural networks include mostly applications in financial forecasting and trading strategies (Roghani 2015) and also in programming tips for new or experienced users (Hagan 2014), (Shaffer 2015).

HYBRID INTELLIGENT SYSTEMS

Key-Terms and Definitions

Usually complex domain problems are ill-defined, difficult to model and demand large solution spaces to be explored. Any relevant information about these problems is the prior domain knowledge, usually incomplete, and input-output instances of the system's behaviour, which is also incomplete. Therefore, in many cases, hybrid combinations seem proper to handle approximate reasoning for these domains, and thus often prove superior in performance comparison to their single compu-

tational intelligent components, thus providing researchers and data analysts with advanced problem solving tools.

Hybrid computational intelligence is defined as any effective combination of intelligent techniques that performs superior or, in a competitive way to simple standard intelligent techniques. Hybrid intelligence was in fact attempted in several scientific papers during the 90s, as an extension to the standard experimentation with most of the well-known intelligent techniques, in various application domains.

Hybrid intelligent systems denote software systems which employ in parallel a combination of methods and techniques from artificial intelligence subfields such as neuro-fuzzy systems, fuzzy expert systems, evolutionary neural networks, genetic fuzzy systems, or other combination and generally combinations of main CI techniques, i.e. neural, fuzzy, evolutionary, and machine learning techniques and algorithms.

In IJHIS⁴ the interest is in research reports “that involve the use of two or more intelligent techniques and approaches, such as neural networks, traditional knowledge-based methods, fuzzy techniques, genetic algorithms, agent-based techniques, case based reasoning etc. The combination or integration of more distinct methodologies can be done in any form, either by a modular integration of two or more intelligent methodologies, which maintains the identity of each methodology or, by fusing one methodology into another, or by transforming the knowledge representation in one methodology into another form of representation characteristic to another methodology”.

Among the topics of interest of the journal are included integrations of Neural Networks with Expert Systems, integrations of Neural Networks with Fuzzy Systems, integrations of Neural Networks with Global Optimization Algorithms knowledge-based neural networks, fuzzy Logic and Expert Systems, integration of Fuzzy Systems with Global Optimization Algorithms, hybrid Optimization Techniques (global, local search techniques etc.), hybrid Systems using

Neural Networks, Evolutionary Algorithms and Fuzzy Systems, integration of Intelligent/Computational Techniques with Information Systems for Data Mining, Knowledge Management, Decision Support, hybridization of Soft Computing with other Machine Learning Techniques (such as Support Vector Machines, Rough Sets, Bayesian Networks, Probabilistic Reasoning, Statistical Learning), Hybrid models using Case-Based Reasoning, Inductive Logic Programming, Grammatical Inference and Hybrid Intelligent Systems Applications to various domains such as Image and Signal Processing, Control and Automation, Industrial and Medical Diagnosis, Bioinformatics, Data Mining, Business Information Systems, E-commerce, E-learning, Intelligent Tutoring Systems, Web Mining, Decision Support Systems, Text Mining, Natural Language Processing, etc.

One of the first attempts to organize events related to hybrid intelligence was the special issue of IEEE Transactions on Neural Networks and Hybrid Intelligent Models (Lee Giles et al., 1998). Later was organized a series of related annual world conferences initiated in Australia (HIS, 2001), lasting till now (HIS 2013; HIS 2014). In addition, since 2006 another similar event was formed in Salamanca, Spain (HAIS 2006) lasting also until nowadays (HAIS, 2013; HAIS, 2016) with long success and interesting topics. These conferences are mostly dealing with applications of hybrid approaches in real world complex problems, involving imprecision, uncertainty, vagueness and high-dimensionality. Also Ling et al. (2014) have announced a special issue in hybrid intelligent methods for health technologies.

Hybrid Intelligence, has also been one of the central topics of attention and focus for the European Network of Excellence called EUNITE, see (EUNITE, 2001) and NISIS, Nature Inspired Smart Information Systems, see (NISIS, 2005). In EUNITE (2001), it was stated that “intelligent hybrid systems” are meant to be any combinations of intelligent technologies (e.g. neuro-fuzzy approaches, evolutionary optimized networks, etc.) but particularly those, which prove to have

an obvious advantage in their performance when applied in complex domains of application (either by means of accuracy obtained, or by means of comprehensibility of the acquired results). An obvious need has been identified for guidelines regarding design, testing and assessment, as well as a need for improved understanding of the fundamental nature of engineering systems with embedded hybrid intelligence.

Hybrid Intelligence Modelling

It should be clear that hybrid intelligence should be used only in cases where its performance proves superior to simple intelligent approaches, in terms of accuracy of the model produced, in tasks like classification, discrimination, clustering, etc., and also in cases where it increases comprehensibility of the resulting model, i.e. production of meaningful rules, relations, or solution representations. In this sense, prior to the construction of a hybrid intelligence scheme, the analyst should attempt to approach and model his problem with the existing standard approaches.

The partial components of a hybrid intelligent system should be able to collaborate efficiently between them. Another important factor of a hybrid system is the speed of process and the time needed to produce a generalized high-performance decision model. Very slowly evolving hybrid schemes (which are often the case) are not desirable, especially in very complex domains of application. Evidence drawn from literature on the effectiveness of a specific kind of hybrid methodologies in a variety of real-world applications could render this hybrid scheme over time as method of choice for the decision maker.

The decision on whether to use a hybrid intelligent methodology or not, lies in long experience and experimentation in comparison to standard intelligent approaches. When partial stages of the overall problem to be solved, seem better to be manipulated by different intelligent techniques (e.g. cluster formation, feature selection for reduction of complexity and so forth), then a hybrid

intelligent model should be applied for a better handling of the problem.

For the selection of the appropriate parts of a hybrid intelligent methodology, the advantages and disadvantages of each of the standard intelligent techniques should be taken into account. Inductive machine learning has always performed highly as a feature selection method for reducing complexity of the search space, especially (1) when entropy information criteria are applied, and (2) when the decision maker tries to analyse nominal data. It is also used as a pattern search mechanism within large collections of data, in order to apply later formal statistics for accepting or rejecting complex hypotheses. Models of evolutionary computation, genetic programming, etc., are time consuming in the training phase, so the decision maker should be aware of the complexity involved. On the other hand, they perform very well in generalization and robust model building from complex data. Fuzzy rule based approaches are by far advantageous in the handling of approximate or vague concepts defined, or existing, within a set of data. Finally, neural networks as stated above are typical black-box architectures (i.e. of very low comprehensibility of the produced decision model) that prove superior in handling numerical data and highly non-linear domains of application. Recent hybrid intelligent approaches can be found in (Siddique & Adeli 2013; Yang 2013).

Neuro-Fuzzy Systems

Neuro-fuzzy systems also called as neuro-fuzzy systems and techniques (NAISO 2002), are definitely the most popular hybrid intelligent systems in literature, due to the fact that they are fast, accurate and efficient approach, and can be understood, designed and implemented easily in automated computing environments. Neuro-fuzzy systems have shown a high rate of success when applied in complex domains of application, either when fuzzy set theory is the heart of such a system, or when the neural mechanism is the dominant component in the architecture. Neuro-fuzzy systems

are usually superior to simple neural networks, due to the fact that a neural network “suffers” from noise, whereas the neuro-fuzzy system has the ability to “absorb” the noise with the use of the embedded membership functions. For similar reasons, a neuro-fuzzy system is superior to a simple fuzzy system, as the neuro-fuzzy systems do not have to tune oneself the rule-base. The main principle of this combination, as seen by a neural network expert, can be roughly described as the adoption of fuzzy functions in (mostly consisted of 3-layers) neural networks’ nodes. On the other hand, a fuzzy systems’ expert may realize a neural-like training such as back-propagation for the membership functions of a fuzzy system. However, combinations and approaches in these hybrid systems can be less obvious and descriptive, concerning different neural or fuzzy structures, such as self-organizing maps or, radial basis functions. Generally the reader should also have in mind that the nature, the reliability and the availability of the data under processing, consist sometimes also a crucial factor for the success or the failure of a specific hybrid intelligent methodology. In their book (Siddique & Adeli, 2013), present advances in neuro-fuzzy systems. An interesting recent survey of the well-established neuro-fuzzy systems can be found in (Viharos & Kis, 2015).

Fuzzy-Evolutionary Systems

Fuzzy-evolutionary systems, in literature also found as evolving-fuzzy systems (EFS 2006; Cordon et al 2001; Kazabov, 2007; GECCO 2007; Lughofer, 2011) are also popular, used in the same complex domains as with the fuzzy-neural systems. Genetic algorithms and fuzzy logic have been used in the past collaboratively for various control engineering applications and complex optimisation problems. Both, fuzzy logic driven genetic approaches and genetic driven fuzzy logic based schemes have been proved effective in modern AI literature. The fuzzy logic driven genetic approaches primarily concern the use of fuzzy logic, either for genetic parameters’ tuning,

or for fuzzy encoding of the chromosomes. The genetic driven fuzzy logic based schemes usually consist of fuzzy rule-based systems, using a genetic approach for the determination of the rule base. An advantage of some of the fuzzy-evolutionary systems is considered the incorporation of fuzzy logic into an evolutionary algorithm. This fact makes hybrid schemes working effectively in a larger scale of application domains. Fuzzy-genetic systems are preferable than simple fuzzy systems, due to the fact that fuzzy-genetic approaches do not have to define oneself the rule-base. Recent advances in evolutionary fuzzy systems can be found in (Siddique & Adeli, 2013).

Neural Networks and Evolutionary Algorithms

The idea behind the implementation of such hybrid systems is the adoption of an evolutionary algorithm for the determination of neural network's weights or the neural network's architecture, or both. In the first case, neural networks are tuned by evolutionary algorithms, rather than generated by, which is the case in the second approach. The third approach may contain both generation and tuning. A special case of tree-like neural networks may also be served by genetic programming training. An interesting work on neuro-evolution is presented by Sher (2012). Also Siddique and Adeli (2013) give advances in evolutionary neural systems.

Machine Learning and Fuzzy Logic

Fuzzy logic is used for the modelling of ambiguity contained in decision attributes, before these attributes are subjected to further process using machine learning for classification and diagnosis tasks. The process followed for the definition of boundaries of the examined attributes, are defined by methods often called "fuzzy or soft thresholds". On the other hand, machine learning can assist the formation of fuzzy membership functions by defining successfully the fuzzy boundaries among neighbouring linguistic areas.

Machine Learning and Evolutionary Algorithms

Machine learning often works as feature selection or feature extraction methodology applied in large collections of data, prior to the application of evolutionary approaches for generalization from data. In this way, machine learning works as a mechanism for reducing complexity, a task which is necessary for time-consuming approaches such as evolutionary computation. Regarding the existence of successful hybrid intelligent methodologies in related literature, irrespective of the application area, approaches related to fuzzy control, function approximation, forecasting, knowledge discovery, decision making, scheduling, feature selection, system design, data classification and image processing can be found, e.g. see (Tsakonas & Dounias, 2002).

Other Hybrid Intelligent Schemes

There exist also intelligent hybrid systems that combine intelligent techniques with other standard mathematical methodologies. We define as *Type I - Hybrid*, those "hybrid" systems that combine two or more well-known intelligent techniques in a sensible methodological scheme in order to obtain a superior intelligent performance in complex domains of application. Similarly we define as *Type II - Hybrid*, those systems that combine a well-known intelligent technique and a standard mathematical or heuristic method, in order to effectively handle complex problems, still preserving the intelligence of the overall approach (Dounias 2003). Examples of this kind are fuzzy inference system optimization using global optimization algorithms, artificial neural network optimization using global optimization techniques, fuzzy clustering algorithms and optimization techniques, hybrid optimization techniques containing simulated annealing, tabu search, GRASP, case-based reasoning, etc., hybridization of soft computing and statistical learning techniques, hybridization with quantum computing, DNA computing, membrane computing and more.

FUTURE RESEARCH DIRECTIONS

Future research directions aim towards the production of user friendly computational environments for combining intelligent techniques and algorithms in handy and powerful hybrid formations, as well as towards the implementation of hybrid intelligent schemes within parallel computational architectures (computer clusters, cloud computing schemes) in order to reduce the time needed for the training of the algorithms and for the production of generalized solutions and models.

Hybrid intelligent systems keep developing in all kinds of data analysis problems like classification, optimization, forecasting, clustering etc. Among the most promising applications in the near future can be found in:

- Management, economics and finance (Sztandera, 2014), with applications in customer segmentation for direct marketing, customer profiling for relationship management, efficient mailing campaigns, customer retention, identification of cross-selling opportunities, credit score analysis, detection of fraudulent behavior and transactions, hedge fund strategies, etc.
- Tsutsui and Collet (2013) presenting various evolutionary methods with successful results from real-world problems in data mining, bioinformatics, drug discovery, crystallography, artificial chemistries, and sudoku.
- Iba and Noman (2016) referring to gene regulatory networks (GRN), covering sub-domains of GRN research such as expression profile analysis, reverse engineering, GRN evolution, and other applications related to systems biology, computational biology, and synthetic biology.

Incremental Approach to Classification Learning

A

Xenia Alexandre Naidenova

Research Centre of Military Medical Academy – Saint Petersburg, Russia

INTRODUCTION

By classification we mean partition of a given object's set into disjoint blocks or classes. We assume that objects are described by a set U of symbolic or numeric attributes and each object can have one and only one value of each attribute. Then each attribute generates, by its values, partition of a given set of objects into mutually disjoint classes the number of which is equal to the number of values of this attribute. To give a target classification of objects, we use an additional attribute KL not belonging to U . In Table 1, we have two classes: $KL+$ (positive objects) and $KL-$ (negative objects).

By classification learning we mean approximation of given object classification in terms of attributes names or values of attributes (Naidenova, 2012). This approximation is reduced to extracting logical rules in the form of functional or implicative dependencies from observable datasets. These dependencies allow to distinguish between classes of given classification. For our example in Table 1, we have some rules based on implicative (ID) and functional dependencies (FD): $Color_of_Hairs, Color_of_Eyes \rightarrow KL$ (FD); if Blond, Blue, then $KL = "+"$; if Hazel, then $KL = "-"$; if Brown, Blue, then $KL = "-"$ (IDs).

The task of classification learning based on inferring implicative rules is equivalent to the task of concept formation (Banerji, 1969, Ganter & Wille, 1999). The goal of this task is to describe/classify new objects according to description/classification of existing objects. Inferring good diagnostic (classification) tests (GDTs) is the formation of the best descriptions of a given object

class $KL+$ against the objects not belonging to this class ($KL-$).

Let $M = (\cup \text{dom}(\text{attr}), \text{attr} \in U)$, where $\text{dom}(\text{attr})$ is the set of all values of attr . Let $X \subseteq M$ and G be the set of indices of objects considered (objects for short), $G = G+ \cup G-$, where $G+$ and $G-$ the sets of positive and negative objects, respectively. Denote by $d(g)$ the description of object $g \in G$. Let $P(X) = \{g \mid g \in G, X \subseteq d(g)\}$. We call $P(X)$ the interpretation of X in the power set 2^G . If $P(X)$ contains only positive objects and the number of these objects more than 2, then we call X a description of some positive objects and $(P(X), X)$ a test for positive objects. Let us define a good test or good description of objects.

Definition 1: A set $X \subseteq M$ of attribute values is a good description of positive (negative) objects if and only if it is the description of these objects and no such subset $Y \subseteq M$ exists, that $P(X) \subset P(Y) \subseteq G+ (\subseteq G-)$.

Table 1. Example of classification

Index of Example	Height	Color of Hair	Color of Eyes	KL
1	Low	Blond	Blue	+
2	Low	Brown	Blue	-
3	Tall	Brown	Hazel	-
4	Tall	Blond	Hazel	-
5	Tall	Brown	Blue	-
6	Low	Red	Blue	-
7	Tall	Red	Blue	+
8	Tall	Blond	Blue	+

DOI: 10.4018/978-1-5225-2255-3.ch017

It has been shown (Naidenova, 1992) that the problem of good tests inferring is reduced to searching for implicative dependencies in the form $X \rightarrow v$, $X \subseteq M$, $v \in \text{dom}(\text{KL})$ for all positive (negative) objects.

The concept of good classification (diagnostic) test has firstly been introduced in (Naidenova & Polegaeva, 1986). In (Naidenova, 2012), it is considered the link between classification learning based on inferring good tests and formal concepts in the FCA.

BACKGROUND DEFINITIONS

Let $G = \{1, 2, \dots, N\}$ be the set of objects' indices (objects, for short) and $M = \{m_1, m_2, \dots, m_j, \dots, m_q\}$ be the set of attributes' values (values, for short). Each object is described by a set of values from M . The object descriptions are represented by rows of a table R the columns of which are associated with the attributes taking their values in M . Let $D(+)$ and $G(+)$ be the sets of positive object descriptions and the set of indices of these objects, respectively. Then $D(-) = D/D(+)$ and $G- = G/G+$ are the sets of negative object descriptions and indices of these objects, respectively.

The definition of good tests as a dual construction or formal concept is based on two mapping $2^G \rightarrow 2^M$, $2^M \rightarrow 2^G$ determined as follows. $A \subseteq G$, $B \subseteq M$. Denote by B_i , $B_i \subseteq M$, $i = 1, \dots, N$ the description of object with index i . We define the relations $2^G \rightarrow 2^M$, $2^M \rightarrow 2^G$ as follows: $A' = \text{val}(A) = \{\text{intersection of all } B_i: B_i \subseteq M, i \in A\}$ and $B' = \text{obj}(B) = \{i: i \in G, B \subseteq B_i\}$. These mapping are the Galois's correspondences (Ore, 1944). Of course, we have $\text{obj}(B) = \{\text{intersection of all } \text{obj}(m): \text{obj}(m) \subseteq G, m \in B\}$. Operations $\text{val}(A)$, $\text{obj}(B)$ are reasoning operations (derivation operations).

We introduce two generalization operations: $\text{generalization_of}(B) = B'' =$; $\text{generalization_of}(A) = A'' =$. These operations are the closure operations (Ore, 1944).

A set A is closed if $A = \text{obj}(\text{val}(A))$. A set B is closed, if $B = \text{val}(\text{obj}(B))$. For $g \in G$ and m

$\in M$, g' is called object intent and m' is called value extent.

By using the dataset in Table 1, we illustrate the derivation and generalization operations: $A = \{7, 8\}$, $\text{val}(A) = \{\text{Tall, Blue}\}$; $A'' = \text{obj}(\{\text{Tall Blue}\}) = \{5, 7, 8\}$;

$m = \{\text{Red}\}$, $\text{obj}(\{m\}) = \{6, 7\}$; $m'' = \text{val}(\{6, 7\}) = \{\text{Red, Blue}\}$;

$B = \{\text{Low, Blue}\}$, $\text{obj}(\{B\}) = \{1, 2, 6\}$; $B'' = \text{val}(\{1, 2, 6\}) = \{\text{Low, Blue}\} = B$.

Classification of objects are defined as follows (Kuznetsov, 1999). Let a context $K = (G, M, I)$ be given, where $I \subseteq G \times M$. In addition to values of M , a target value $\omega \notin M$ is considered. The set of objects G is partitioned into two subsets: $G+$ of objects with property ω (positive objects) and $G-$ without this property (negative objects).

Then $K = K+ \cup K-$; $K+ \cap K- = \emptyset$; $K+ = (G+, M, I+)$; $K- = (G-, M, I-)$; $G = G+ \cup G-$; $G+ \cap G- = \emptyset$.

Diagnostic test is defined as follows.

Definition 2: A diagnostic test for $G+$ is a pair (A, B) such that $B \subseteq M$ ($A = \text{obj}(B) \neq \emptyset$), $A \subseteq G+$, and $\forall g, g \in G-: B \not\subseteq \text{val}(g)$ and $B \neq \text{val}(g)$.

Definition 3: A diagnostic test (A, B) such that $B \subseteq M$ ($A = \text{obj}(B) \neq \emptyset$) is a good test for $G+$ if and only if extension $A^* = A \cup g$, $g \notin A$, $g \in G+$ implies that $(A^*, \text{val}(A^*))$ is **not a test** for $G+$.

Definition 4: A diagnostic test (A, B) , $B \subseteq M$ ($A = \text{obj}(B) \neq \emptyset$) is a good maximally redundant test (GMRT) for $G+$ if any extension $B^* = B \cup m$, $m \notin B$, $m \in M$ implies that $\text{obj}(B^*) \subseteq \text{obj}(B)$ ($(\text{obj}(B^*), B^*)$ is a test for $G+$ but not good).

It is important to note that if a pair (A, B) is a maximally redundant test, then A and B are closed and, consequently, this test is a formal concept in terms of the Formal Concept Analysis (the FCA)

(Ganter and Wille, 1999). But, in general case, diagnostic test is not obligatory a formal concept (Naidenova, 2012).

Definition 5: A diagnostic test (A, B) , $B \subseteq M$ ($A = \text{obj}(B) \neq \emptyset$) is a good irredundant test (GIRT) for $G+$ if any narrowing $B^* = B \setminus m$, $m \in B$, $m \in M$ implies that $(\text{obj}(B^*), B^*)$ is not a test for $G+$.

If a good test (A, B) for $G+$ is irredundant, then any narrowing $B^* = B \setminus m$, $m \in B$, $m \in M$ implies that $(\text{obj}(B^*), B^*)$ is not a test for $G+$. If a good test (A, B) for $G+$ is maximally redundant, then any extension $B^* = B \cup m$, $m \notin B$, $m \in M$ implies that $(\text{obj}(B^*), B^*)$ is not a good test for $G+$.

Definitions 2, 3, 4, 5 remain true if $G+$ is replaced by $G-$.

In what follows, we are interested in inferring GMRT or good concepts (GCs).

Some examples of formal concepts are in Table 2. Let us check if a pair $(A, B) = ((5, 6), (\text{Rain}, \text{Cool}, \text{Normal}))$ is a concept or not. It is a concept, because $\text{val}(5, 6) = (\text{Rain}, \text{Cool}, \text{Normal}) = B$, $\text{obj}((\text{Rain}, \text{Cool}, \text{Normal})) = (5, 6) = A$. However, this concept doesn't distinguish the classes of

objects (it is not a test for both $k+$ and $k-$). Pair $((3, 13), (\text{Overcast}, \text{Hot}, \text{No}))$ is a concept for $k(-)$, but not a good one, because there is pair $((3, 7, 12, 13) (\text{Overcast}))$ such that $(3, 13) \subset (3, 7, 12, 13)$.

A

INCREMENTAL LEARNING GOOD CONCEPTS

Incremental concept learning is very useful for many information retrieval applications related to the changeable environment. For example, mining high utility itemsets in dynamic databases (Asha et al., 2014), intrusion detection (Fan, et al., 2013; Chen et al., 2016), Web page classification (Ciarelli et al., 2014), association rule mining (Duaimi & Salman, 2014), constructing dynamic information systems (Liu et al., 2011; Liu, et al. 2014), and many others.

To transform inferring good formal concepts (GCs) into an incremental process, there are two kinds of subtasks:

- To find all GCs intents of which are included in the description of an object (the first kind subtask); and

Table 2. Examples of formal concepts

G	Outlook	Temperature	Humidity	Windy	Class
1	Sunny	Hot	High	No	$k(+)$
2	Sunny	Hot	High	Yes	$k(+)$
3	Overcast	Hot	High	No	$k(-)$
4	Rain	Mild	High	No	$k(-)$
5	Rain	Cool	Normal	No	$k(-)$
6	Rain	Cool	Normal	Yes	$k(+)$
7	Overcast	Cool	Normal	Yes	$k(-)$
8	Sunny	Mild	High	No	$k(+)$
9	Sunny	Cool	Normal	No	$k(-)$
10	Rain	Mild	Normal	No	$k(-)$
11	Sunny	Mild	Normal	Yes	$k(-)$
12	Overcast	Mild	High	Yes	$k(-)$
13	Overcast	Hot	Normal	No	$k(-)$
14	Rain	Mild	High	Yes	$k(+)$

- To find all GCs including a given set of values (the second kind subtask).

For solving these subtasks, we need to form sub-contexts of a given classification context. The following notions of object and value projections are developed to form sub-contexts.

Definition 6: Object projection $\text{proj}(d)$ of a positive object description d on the set $D+$, i.e. descriptions of all positive objects, is equal to $Z = \{z: z = d \cap d^* \neq \emptyset, d^* \in D+ \text{ and } z \text{ is the intent of a test for } G+\}$.

An example of object projection $\text{proj}(d_3)$ on $D(-)$ is $\{z_1; z_2; z_3; z_4\}$ (see, please Table 3).

Definition 7: The value projection $\text{proj}(B)$ on a given set $D+$ is $\text{proj}(B) = \{d: B \subseteq d, d \in D+\}$.

An example of value projection $\text{proj}(\text{Cool})$ on $D(-)$ is $\{d_5; d_7; d_9\}$ (see, please, Table 4).

In order to find all GCs in an object or value projection, it is possible to use any of well known algorithms for inferring GCs (Naidenova, 2006;

Naidenova & Parkhomenko, 2013; Godin et al., 1995). We shall concentrate on the problem of incrementally change a set of GCs in changeable classification contexts when an object or value is added or removed from consideration.

FUTURE RESEARCH DIRECTIONS: FOUR CASES OF INCREMENTAL LEARNING GCs

The GCs are the minimal formal concepts by the definition in (Ganter & Kuznetsov, 2000). Incremental learning the formal concepts requires an algorithm of Galois lattice incremental construction from data. In this process, it is generally assumed that the data (objects, itemsets, or transactions) are added gradually but not deleted. Much attention has been paid in recent years to the problem of concept lattice incremental construction (Godin et al., 1995; Kourie et al., 2009; Van der Merwe et al., 2004; Outrata, 2013). An algorithm of incremental generating GCs has been proposed in (Naidenova, 2006) and investigated in more detail in (Naidenova & Parkhomenko, 2013).

Table 3. An example of object projection

G	Outlook	Temperature	Humidity	Windy	Class	DT ? Z
1	Sunny	Hot	High	No	k(+)	
2	Sunny	Hot	High	Yes	k(+)	
3	Overcast	Hot	High	No	k(-)	Z1, yes
4	Rain	Mild	High	No	k(-)	no
5	Rain	Cool	Normal	No	k(-)	no
6	Rain	Cool	Normal	Yes	k(+)	
7	Overcast	Cool	Normal	Yes	k(-)	Z2, Yes
8	Sunny	Mild	High	No	k(+)	
9	Sunny	Cool	Normal	No	k(-)	no
10	Rain	Mild	Normal	No	k(-)	
11	Sunny	Mild	Normal	Yes	k(-)	
12	Overcast	Mild	High	Yes	k(-)	Z3
13	Overcast	Hot	Normal	No	k(-)	Z4
14	Rain	Mild	High	Yes	k(+)	

Table 4. An Example of value projection

G	Outlook	Temperature	Humidity	Windy	Class
1	Sunny	Hot	High	No	k(+)
2	Sunny	Hot	High	Yes	k(+)
3	Overcast	Hot	High	No	k(-)
4	Rain	Mild	High	No	k(-)
5	Rain	Cool	Normal	No	k(-)
6	Rain	Cool	Normal	Yes	k(+)
7	Overcast	Cool	Normal	Yes	k(-)
8	Sunny	Mild	High	No	k(+)
9	Sunny	Cool	Normal	No	k(-)
10	Rain	Mild	Normal	No	k(-)
11	Sunny	Mild	Normal	Yes	k(-)
12	Overcast	Mild	High	Yes	k(-)
13	Overcast	Hot	Normal	No	k(-)
14	Rain	Mild	High	Yes	k(+)

On the other hand, there is a practical demand to modify the concept lattice already constructed under dynamic data changes. In this case, it is necessary to consider both adding and deleting the data (objects, attributes). This problem is not yet investigated sufficiently. Deleting objects (and only objects) is considered in Carpineto and Romano (2004) and Zhang et al. (2013). In the first paper, algorithm *RemoveObject* is advanced, in the second one, algorithm *DeleteObject* is proposed. These algorithms have been essentially improved with respect to their computational complexity in Zou et al. (2015) in newly proposed algorithm *FastDeletion*.

However modifying the formal classification contexts can be required not only by adding or deleting objects but also by adding or deleting attributes (values). Such a modification of concept lattice is even less explored than deleting objects. Of interest in this regard, the article (Kauer & Krupka, 2014), in which the problem of removing an incidence from a formal context is solved.

The four variants of changing formal contexts are considered in (Carpineto & Romano, 2004). Recent publication on this topic (Oustrata, 2013)

provides an efficient algorithm of modifying the formal contexts by adding objects, which may include, in their descriptions, some new attributes. Modification of the order relation in concept lattice is also determined. The proposed algorithm defines new and modified concepts without using previously built lattice but considering the only available data. It is based on algorithm *Close-by-One* (CbO) of generating formal concepts (Kuznetsov, 1993) and its next refinements *FCbO* (Oustrata, 2012) and *PFCbO* (Oustrata, 2010). As for removing objects, this process is reduced to adding objects. The paper (Wray et al., 2016) presents an implementation and evaluation of the *ECbO* updated algorithm.

We propose four cases of modifying classification contexts: adding/removing objects and adding/removing values of attributes. New and modified GCs are determined. Modification of GCs is based on a decomposition of formal classification contexts into value and object sub-contexts and using an incremental algorithm for inferring GCs in these sub-contexts (Naidenova & Parkhomenko, 2013; Naidenova et al., 2015).

Case 1

Suppose that each new object comes with the indication of its class membership. The following actions are necessary:

1. Checking whether it is possible to enlarge the extents of some existing GCs for the class to which a new object belongs (a class of positive objects, for certainty);
2. Inferring all GCs, intents of which are included into the new object description; for this goal, we use the first kind subtask; and
3. Checking the validity of GCs for negative objects, and, if it is necessary, modifying invalid GCs (test for negative objects is invalid if its intent is included in a new (positive) object description); for this goal, we use the second kind subtask.

Let $STGOOD+$ and $STGOOD-$ be the current sets of GCs for positive and negative class of objects, respectively, and M be the set of all attribute values used for object descriptions.

Let $GC \in STGOOD-$ and $Y = \text{intent}(GC)$. If $Y \subseteq \text{tnew}(+)$, where $\text{tnew}(+)$ is the description of a new positive object, then GC should be deleted from $STGOOD-$.

For correcting the GC, we have to find all $X \subseteq M$ such that $Y, Y \subseteq M, Y \subseteq X$, and $(\text{extent}(X), X)$ is a GC_{new} for $G-$.

Consider an example of adding object in the process of inferring CGs for the data in Table 2.

Let us fix the K with first 6 objects and add 7th object description. As a result, $GC = ((2,6), (\text{Yes}))$ for $k(+)$ becomes invalid, and a new GC for $k(-)$ appears $((3,7), (\text{Overcast}))$ (Table 5).

Case 2

Suppose that an object is deleted from a classification context. The following actions are necessary:

1. Selecting the set GC_{sub} of $STGOOD+$ ($STGOOD-$) containing deleted object in their extents; and
2. Modifying concepts of GC_{sub} by removing the deleted object from their extents.

After modifying a GC in GC_{sub} , we have the following possibilities:

- Intent of GC_{new} is not changed ($\text{intent}(GC_{\text{new}}) = \text{intent}(GC)$). Then GC_{new} is a good concept in modified context; and
- $\text{Intent}(GC_{\text{new}}) \neq \text{intent}(GC)$ and $\text{extent}(GC_{\text{new}})$ is included in the extent of an existing GC in $STGOOD+$ ($STGOOD-$), then GC_{new} can be deleted; else this GC_{new} is a good concept in the modified context.

Let us fix the whole classification context (Table 2) and all the GCs obtained in this context (Table 6) and delete object 9. The following result: $GC = ((5,10,13), (\text{Normal}, \text{No}))$ remains, $GC = ((11), \text{val}(11))$ is deleted, because it is not good.

Table 5. Adding object (see, please, Table 4)

G	Extents of GCs (Current Situation)
Current objects (1;...; 6)	Extents of GCs in $STGOOD(+) = \{(1, 2); (2, 6)\}$, Extents of GCs in $STGOOD(-) = \{(3); (4, 5)\}$
Adding object 7	Extents of GCs in $STGOOD(+) = \{(1, 2), (6)\}$, Extents of GCs in $STGOOD(-) = \{(3, 7), (4, 5)\}$

Table 6. Deleting an object

GCs(-)	GCs(+)
$((1; 2; 8), \text{Sunny High})$ $((6; 14), \text{Rain Yes})$	$((4; 5; 10), \text{Rain No})$ $((5; 9; 10; 13), \text{Normal No})$ $((10; 11), \text{Mild Normal})$ $((9; 11), \text{Sunny Normal})$ $((3; 7; 12; 13), \text{Overcast})$

Case 3

Suppose that a new value m^* is added to the set M of values. The task of finding all GCs whose intents contain m^* is reduced to the task of the second kind.

Case 4

Suppose that some value m is deleted from consideration. It is necessary to consider two possibilities: $\text{extent}(\text{GC}_{\text{new}}) = \text{extent}(\text{GC})$ and $\text{extent}(\text{GC}) \subset \text{extent}(\text{GC}_{\text{new}})$. In the first case, GC_{new} is a good concept for modified context. In the second case, GC_{new} is not a good concept for modified context. However, the extent of GC_{new} can contain extents of new GCs and these GCs can be obtained by using the subtasks of first or second kind.

Some words about incremental pattern recognition based on GCs. Recognizing the class membership for a new object not belonging to training set is performed as follows:

- If (and only if) description of object contains an intent of GC of only one class, then the object can be assigned to this class;
- If description of object contains intents of GCs of both Class^+ and Class^- , then we have the case of contradiction; and
- If description of an object does not contain any intent of GCs, then we have the case of uncertainty.

In two last cases, it is necessary to continue learning by adding new objects or to change the classification context.

This approach to incremental learning GMRTs (GCs) has been applied to analyzing the intellectual development of medical cadets (Naidenova et al., 2016).

CONCLUSION

It is proposed a model of incremental classification learning based on incremental inferring good formal concept and their correcting in changeable classification contexts.

KEY TERMS AND DEFINITIONS

Diagnostic or Classification Test: Assume that we have two sets of objects’ examples called positive and negative examples, respectively. A test for a subset of positive examples is a collection of attributes’ values describing this subset of examples, i.e. it is common or general feature for all examples of this subset and, simultaneously, none of the negative examples is described by it.

Good Classification Test: A classification test describing a given set of positive examples is good if this set of positive examples is maximal in the sense that if we add to it any positive example not belonging to it, then the collection of attributes’ values describing the obtained set will describe at least one negative example.

Good Irredundant Classification Test (GIRT): A good test is irredundant if deleting any attribute’s value from it changes its property “to be test” into the property “not to be a test”.

Good Maximally Redundant Classification Test: (GMRT): A good test is a maximally redundant one if extending it by any attribute’s value not belonging to it changes its property “to be a good test” into the property “to be a test but not a good one”.

Incremental Learning: Incremental learning is a machine learning paradigm where the learning process takes place whenever new example(s) or new attribute(s) (attribute value(s)) merge or must be deleted from dataset and the solutions already obtained are only modified.

The Subtask of the First Kind: Assume that we have two sets of positive and negative examples and a positive example. The subtask of the first

kind is to find all the collections of attributes' values that are included in the description of this example and correspond to the good tests (GMRTs or GIRTs) for the set of positive examples.

The Subtask of the Second Kind: For a given set of positive and negative examples and a non-empty collection of attributes' values such that it does not correspond to a test for the set of positive examples, find all GMRTs (GIRTs) containing it.

A

Machine Dreaming

James Frederic Pagel

University of Colorado School of Medicine, USA

INTRODUCTION

From the anthropomorphic perspective, dreaming is restricted to humans, the only organism with a cognitive processing system able to report what is perceived to be a dream. Dream equivalent processing as based on shared characteristics and human based definitions are, however, within the capacity of modern computer systems. In the human, dreaming and dream-like cognition is utilized in functions with individual and species survival value including: feedback into sleep-associated operative processing, emotional integration (particularly as part of the response to significant physical and/or psychological stress), alternative problem solving, threat avoidance, and creativity (Pagel, 2008; Revonsuo, Tuominen, & Valli, 2015). AI and other machine systems are being developed with the capacity for accomplishing dream-like mentation. This goal is not routinely stated and is in many cases not understood as part of the objective by the programmers and theorists involved in the process. But current predicate logic systems have demonstrated set limitations in their ability to function in the common-sense human environment (Parisi, 2007). Particularly in robotics, an obvious need has developed for systems able to integrate and interact better with humans in the same manner that humans interact with one another. In order for systems to function in the common-sense based human environment better than systems limited to predicate logic, they are likely to require the capacity for achieving human equivalent processing capabilities. As based on many of the defined criteria for dreaming, some current machine systems have been developed utilizing both hardware and software that can function in a dream equivalent manner.

DOI: 10.4018/978-1-5225-2255-3.ch018

BACKGROUND: THE PROBLEM OF DREAM DEFINITION

Dreaming is an almost ubiquitous personal experience, and as such, many definitions for dreaming have been developed and routinely utilized. For each individual experiencing dreaming, the experience seems concrete and obvious. There has been a strong tendency for each individual dreamer to presume that what he or she experiences as a dream is the same for every other individual who dreams. However, what one individual understands to be a dream is often far different from what another experiences or construes to be a dream. This has led to a situation in which there are multiple definitions and no concrete or overall inclusive definition, so that for any group, a series of often different, recurring and set definitions are used for dream (Pagel & Meyers, 2002). This problem of confused and even contradictory definitions has led to significant problems for researchers and investigators in the fields of dream study. For the sleep physician dreams are sleep-associated mental activity. For the psychoanalyst, dreaming defined by bizarre and/or hallucinatory content occurs in both wake and sleep. For one group, dreaming is a state of consciousness. For the other, dreaming is a form or type of thought. In some epistemologies, even the oldest of definitions, such as the dream as a message from god, are still used and believed (Buckley, 2009).

The problem of definition was confounded further in the last decades of the twentieth century when a wide spectrum of neuroscientists and clinicians decided, despite a lack of experimental evidence, that the electrophysiological state of Rapid Eye Movement Sleep (REMS) was equivalent to dreaming. Defined as REMS,

dreaming apparently needed no further definition (Pagel, 2011). Aristotle described a definition as a description of the “essence or essential nature” of the topic and as such, each definition applies and reflects an aspect, an essence of the state (Eco, 1984). In an attempt at clarification, in the year 2001, a multi-specialty panel of dream researchers and therapists developed a multi-axis definition paradigm for dreaming (Table 1) (Pagel, Blagrove, Levin, et. al., 2001).

One approach that can be used to avoid the problems of definition is to limit an approach to the associated and describable characteristics of the state. Researchers avoid defining ‘dream’ and focus on measurable factors (variables) known to be associated with the state such as recall frequency, content, and reported effects on waking behavior (Pagel, 2014). Another approach has been to avoid defining dream by concentrating on the known components of the cognitive process such as the associative memories, emotions and non-perceptual imagery that characterize the dreams state. Computer systems can be utilized to create simulacrum dreamscapes that include these components that comprise a biologic dream. Such artificial dreams are the focus of human filmmakers. The limitations for this process are not technological, they are based on the limits of our current understanding of the state. Computer

systems utilize such capacities at the human interface, and in the presentation of data.

We humans are prone to describing much that is important in our life experience as being ‘like a dream.’ Dreams can be viewed as ‘pictured metaphors’ and as such, these images in metaphor are the stuff of dreams (States, 1997). Metaphor can be used as Aristotle suggested, “to use metaphor well is to discern similarities (to see, and/or analytically get beneath the skin of something).” (Eco, 1984) Yet for dreams, comprised of many and diverse metaphors, the metaphors that we use for specific description are most often misleading, describing only limited aspects of the state. Such metaphors viewed as partial definitions are within the capacity of artificial intelligence (AI) systems.

Some machine based dream equivalents, particularly those based on definitions, are already part of the processing utilized by artificial systems. Some such as Internet based criteria are in the process of assessment, since the system has developed so quickly and with so few controls that it has become somewhat independent and opaque to our understanding. Others, such as the neural-net based systems in current development, give hints of a capacity for dream equivalence, but are able to function, at this point, only at minimalistic levels of consciousness. The interface systems are in some ways the most fascinating, producing shared dream creation and utilization between human and machines.

Table 1. Definitions for dreaming - a classification system paradigm

A Definition of Dream Has Three Characteristic Continua		
Wake/Sleep	Recall	Content
Sleep	No Recall	Awareness
Sleep Onset	Recall	Day-Reflective
Dreamlike States	Content	Imagery
Routine Waking	Associative Content	Narrative
Alert Wake	Written Report	Illogic
	Behavior	Bizarre/ Hallucinatory

MACHINE DREAM EQUIVALENTS

Messages From God

Computers routinely access the operative instructions that are part of their programming. Many computer systems are interactive. As based on level of access, computers are far closer to their creators and controllers than most humans. These communications from interactive creators can be viewed from the machine perspective as messages from their gods. So defined, messages from the

creator, accessible programmed information asserting both the capabilities and limits of expected behavior, can be considered as meeting this definition criteria as a form of machine dreaming.

SLEEP ASSOCIATED MENTATION

Dream equivalents have been proposed to occur during sleep and screensaver mode activity in computer systems, functioning as a form of defragmentation and system cleaning (Crick & Mitchenson, 1983). In biological systems, it has been proposed that it is this process that accounts for the perceived “degraded and/or degenerative” (non-logical) aspects of the dream state (Tononi, 2008). Finite state machines, however, are always in one of the two defined states – on or off. This difference between machine sleep (off) and biologic sleep denotes a profound difference between systems, since there is little if any evidence to suggest that an off-state equivalent is possible for any biologic system that is actually alive. Independent, solitary, finite state machines, as currently designed, do not possess the processing ability within their strictly defined states to support a logical analog for the definition of dreaming as sleep-associated mentation.

In software systems such as the Internet, finite state machines are hardware interconnected nodes within an extended system. Such systems maintain a variable, but always on-mode of interconnected data flow, despite individual nodes dropping out or being turned off. Periods of low data flow in multiplex interconnected systems, correspond to human sleep cycles (Peterson & Davie, 2000). During such system-defined sleep periods, these systems operate closer to optimal performance than during periods of high data flow and congestion (wake). Exceedingly complex processing can occur at lower error rates than during congested periods of wake functioning. These periods can be viewed as periods of ‘internet sleep.’ The cognitive processing occurring during these periods meets definition criteria for dreaming on all three axis’s.

BIZARRE AND HALLUCINATORY MENTATION

The psychoanalytic definition for dreaming (bizarre and hallucinatory mentation derived from the unconscious) is today one of the most commonly utilized definitions. As based on this definition, dreaming is defined by its content. Since such mental activity defined as dreaming is defined by content rather than associated state of consciousness, psychoanalytically defined dreaming can occur during waking as well as during sleep (Pagel, Blagrove, Levin et. al., 2001).

Neural network designed processing systems utilize artificial neuron interconnections. Neural net systems can also include non-digital neuron equivalents, sometimes characterized as analog devices (Cowan & Sharp, 1988). Such systems produce a significant proportion of outcomes that can be considered as indeterminate or hallucinatory, hypothetical and non-applicable to the real world situation. Such results can be interpreted as machine dysfunction. As artificial neural density increases the combinations of confused or logically unusable real number stimuli, noise, and partial or incomplete training increases the probability for significant AI machine dysfunction. Such results are analyzed using outside rules and controls and are rejected if they fit outside expected parameters - a form of data interpretation (Padhy, 2005). The “unusable” results of such processing - degraded, indeterminate and hallucinatory - can be viewed based on definition as a form of machine dreaming (Pagel & Kirstein, 2017).

In order to program neural net systems, formalized versions of nonmonotonic reasoning have been developed. Neural net systems programmed in this manner are more likely than symbolic processors to draw conclusions that might be false even when based on premises that are certainly true (Gillies, 1996). Once an appropriate and functional programming language is in place, neural-net AI systems can then be set up and controlled using feedback loops, fuzzy logic, data weight, and repeated application of simple con-

trol rules (Kosko, 1993; Zahed, 1987). Artificial neural networks incorporating on-off processing, multiple connections, multiple levels, and dynamic feedback taking place in temporal sequence or in artificial pseudo-time space can produce neural equivalent processes of associative, multi-level memory, and cognitive feedback, processes that parody aspects of biologic dreaming.

Neural network systems are most often programmed to discard, ignore or deemphasize results that are inconsistent or out of the range of goals set by the programmer. When the obtained results vary markedly from set expectations, the results utilized will be those consistent with expected outcomes, the researchers' beliefs, or the presenter's aesthetic assuring that "outside - the - box" results will not be considered or included in the analysis. This approach clearly limits the systems' capacity to produce alternative responses. The inclusion of such alternative outcomes may be required for a system to develop the capacity to function in what the complex, and often illogically described human world. Such "machine dreaming" based data integration may be required in order to produce creatively useful results from neural network based computing operations.

REM SLEEP

The discovery of REMS came at the end of the psychoanalytic era. Researchers and theorists adopted the perspective, with almost no proof, that dreaming took place only during REM sleep. The association of REMS with dreaming was interpreted by many as evidence that the 'primitive' brain-stem based state of REMS was equivalent to the psychoanalytic wild child, the mythical 'Id,' from which bizarre content rose up from primitive aspects of the mind (activation), before being integrated and modulated by higher cortex operating systems (Pagel, 2011). The supposition that REMS was dreaming was incorporated into widely accepted theories of neu-

roconsciousness including activation-synthesis, activation-integration-modulation (AIM), reverse learning, neural-net theory, search-attention, and protoconsciousness theory (Hobson, 2011). Any physiological activation taking place in the CNS or in the extended body during REMS was viewed as part of dreaming. The dreaming = REMS correlate became philosophically and neuroscientifically indispensable. Unfortunately there never was any actual evidence that REMS was required for the process of dreaming to occur. The abundance of data indicating that dreaming occurs without REMS was ignored and/or disparaged (Foulks, 1993; Solms, 1997; Solms & Turnbull, 2002). It is only recently that most neuroscientists have been forced to surrender their belief in the equivalence of REMS to dreaming and accept that dreaming and REMS are doubly dissociable states. Currently it is questionable as to whether there is any special association between REMS and dreaming (Pagel, 2011). However, fifty years of neuroscientific research focus, the electrophysiology, neurochemistry, neuroanatomy and associated physical correlates of REMS are among the best described of any CNS state.

At this point in time, we have the technical capacity to artificially create almost anything that we can fully describe. The human CNS is composed of 100 billion neurons connected by 100 trillion synapses, each individually controlled by 80,000 genes (3 billion base pairs) affected and interconnected by multiple electrical, ionic, energy, and chemical systems that exert their effects inside and outside neural pathways. Despite such extreme complexity, the creation of an equivalent artificial system is now considered to be within the realm of technical possibility (Markham, 2009). The brain is subdivided into various pathologically and anatomically differentiated parts with each cortical areas constructed of subunits and pools of cells acting in a coordinated way, columns, cell assemblies, micro-circuits, and networks of individual nerve cells each interconnected by axon and dendritic synaptic interfaces. Individual

neurons interconnected with glial and other neural cells form the basic units of this anatomic system at the microscopic level of scale. Each neuron (cell) is subdivided into compartments, synapses, channels, and molecules each with physiological and dynamical properties. Within and outside the cellular nucleus, the genomic systems of DNA and RNA are variably expressed in response to cellular messenger, protein, pH, ATP, electrolyte, and electrical frequency changes. Extending from the organ brain to the level of DNA coding, the series of integrated levels in the mammal CNS have been postulated to include at least seventeen levels of interactive complexity (Markham, 2014).

CNS complexity extends well beyond the anatomy. The brain's spatial structure functions on a wide and intermingled range of scales in environmental and temporal interaction. Temporally, the electrical, chemical, genetic, and endocrine dynamics of the brain span many orders of magnitude. Synaptic, magnetic, genetic, and electrical processes occur and alter within a sub-millisecond to millisecond range. Perceptual and thought processes happen in fractions of seconds to hours, and memory phenomena last for seconds to many years. Circadian and ultra circadian rhythms relate brain function to the external environment, including the effects of solar and lunar light and tidal cycles. Even slower processes affect the CNS on genetic, molecular, and evolutionary time scales. Each process, each CNS function, is embedded in a network of temporal and structural interactions and dependencies. And each biological system is also a physical system with the characteristics of a liquid, a gas, or a solid, each composed of an interactive atomic and sub-atomic structure.

Despite this level of complexity, major attempts are currently underway to further analyze and then create artificial CNS constructs. The National Institutes of Health have sponsored an initiative called the Human Connectome Project designed to trace and map three-dimensionally brain neural connections (Kurzweil, 2012). At the Allen institute in Seattle, datasets with cel-

lular level spatial resolution are being used to produce cellular transcriptomic profiles of specific genetic expression in defined neuroanatomic regions (Sualin & Hohmann, 2007). Neuromorphic chips have been developed called SyNAPSE each designed to simulate the quarter-million synaptic connections of approximately 250 neurons – with the goal, creation of a simulated neo-cortex with 10 billion neurons (chips) and 100 trillion connections (IBM, 2011). The European Union has invested major research funds into an even more ambitious project through the École Polytechnique Fédérale de Lausanne (EPFL) where Henry Markham leads an approach designed to produce a supercomputer based on multilevel neural network architecture. The initial goal of the project, the simulation of a rat neocortical column, considered by some researchers to be the smallest functional unit of the neocortex, was completed in 2006. In rats, each column is about 2 mm in length, has a diameter of 0.5 mm, containing approximately 10,000 neurons (10^8 synapses). The ultimate goal of this project to allow for the parallel simulation of large numbers of connected columns in order to reconstitute a whole neocortex (in humans about 1 million cortical columns) (Graham-Rowe, 2012). At EPFL, the first-draft digital reconstruction of the microcircuitry of the somatosensory cortex of juvenile rat used cellular and synaptic organizing principles to algorithmically reconstruct detailed anatomy and physiology in a neocortical volume of 0.29 ± 0.01 mm³ containing ~31,000 neurons with 55 layer-specific morphological and 207 morpho-electrical neuron subtypes. This network of digitally reconstructed neurons included ~8 million connections with ~37 million synapses. Physiological electrical fields applied to this system produce a spectrum of network states with a sharp transition from synchronous to asynchronous activity (Markham, Muller, Ramaswamy et al., 2015). Markham has predicted that his laboratory will complete such a system with complexity equivalent to the human CNS within the next ten years (Markham, 2009)

It is potential that such neuroanatomic Zombie neural network systems, and future “perfect” Zombie systems that will incorporate electrophysiological and neurochemical aspects of CNS operations, will have the capacity to parody or approximate physiologic CNS states. Some neuroscience theorists suggest that due to the similarity in their structure and there extreme levels of integrated complexity, such systems may have the capacity for human-equivalent consciousness (Balduzzi & Tononi, 2008; Koch & Tononi, 2008). These systems might even approximate REMS - the disenfranchised, yet persistently believed correlate of dream. Lucid dreaming, conscious awareness and volitional control during dream consciousness, is most often considered as associated with REMS. It is possible that the development of such a pattern of machine lucidity would mark the development of human-equivalent or supra-human consciousness in such a system (Bostrom, 2014). The ethical considerations involved in our creation of such systems are apparently profound.

METAPHOR

Wish fulfillment, a very loosely Freudian construct (dream marriages, dream vacations, dream homes and dream cars) is the most generally utilized definition for dream. We are prone to describing much that is important in our life experience as being ‘like a dream.’ Dreams can be viewed as “pictured metaphors.” Such images in metaphor are the stuff of dreams (States, 1997). The Internet has become a repository where we search for patterns and attempt to consummate our dreams. Some of this search we define, but much of what we define is based on the structure of the Internet, our access systems, the alignment of the search engine that we use, and the slant of the programming applied by outside sources. While hardware systems may lack capacity for the human-like experience required for the creation of human-like dreams, the Internet provides a system data-base of dream metaphor exponentially larger than that

available to any individual human. As based on access to such a database of human dreams, it is well within the capacity of an AI search engine to create dream-equivalent metaphors.

DREAM STRUCTURE: ARTIFICIAL CORRELATES

Almost all dreams include images, emotions and associative memories (Pagel, 2014). Computer systems integrate and analyze digitalized data - words, narrative, emotions, and visual images included in a human based data set. Machine-based imagery constructed out of human and machine based data bits often has a dream-like phenomenology: reflecting waking experience (continuity), and producing a visually unique presentation that is complex, constantly changing, and can be perceived as emotional.

Humans in their art, they’re writing, and their films have concentrated on developing the ability to create artificial dreams. Filmmaking is a process that lends itself to artificial simulation. In our viewing or reading of such constructed dreams, we interject our own memories, emotions and imagery into the experience. Once enmeshed, the filmmaker can entice us into a vicarious experience of mental images that resemble less a dream and more the vivacity of actual experience. This capability has already been integrated in to computer interfaces (ex. IBM’s Watson). Such machine integrated presentations that incorporate and organize experience into humanly assessable formats will be required in order to further develop interface interactions.

MACHINE DREAMS AT THE HUMAN INTERFACE

Many of us spend much of our waking time within a bi-directional machine interface. The interfaced human and the attached machine both become something larger, smarter, and potentially more

interesting than either system when disconnected. After spending waking time interacting with a machine interface, our waking thoughts, our sleep, and our dream contents are altered. (Gackenback & Kurville, 2013). New interface systems under current development will include non-sensory modalities such as frequency-based physiologic electrical fields, extending the capacities of the interface to cognitive systems that more often utilized in meditation, sleep and dream states than in waking perceptual focused attention (Lakatos, Karmos, Mehta, Ulbert, Schroede, 2008; Pagel, 2012). The interface is very likely to extend into shared machine dream equivalents, incorporating memories, visions and emotions into the available data stream.

FUTURE RESEARCH DIRECTIONS

Current computer systems have the ability to represent and process human metaphor, bringing together and interconnecting human-based associated visual and text-based memories into stories that have the characteristics of dreaming mentation. Neural-net systems have the capacity to go even further, bring indeterminate and/or hallucinatory results into the resultant response paradigm. Such results even look like dreamscapes (Google, 2016). It remains debatable as to whether the neuroanatomic and perfect zombie systems that are being created will have the capacity for human-like consciousness. If such a breakthrough does occur, the development of human-like consciousness will likely require that such zombies have a human-like capacity to dream. At that point the machine might potentially enter a state of consciousness in which it attains and exerts control of potential outcomes, controlling its own story. This can be viewed as the attainment of the machine equivalent of lucid dreaming: a state of dream-like consciousness from which the system is able to independently change and control data flow. There will be little question as to whether such a system is conscious.

CONCLUSION

System disconnected FSM's built with predicate, concrete logic programming, such as the typical personal computer, have only minimal capacities for achieving dream-like forms of cognitive processing. But as based on definition, many artificial systems can meet some of the human-based criteria for dreaming (Table 1). The Internet offers access to an expansive database of human dream metaphors and memories. Cloud based operating allows for extension beyond the FSM into a processing approach in which the overall operating system is never turned off including periods of high and low data flow (system sleep). The extension of processing capacity into areas of non-parametric, approximate or fuzzy logic processing, extends system capacity beyond concrete logic applications, and increases the possibility of alternative and/or unexpected outcomes. The addition of an AI self-teaching (learning) capacity to such a system and the utilization of a neural-net hard and software formats for that processing means that a much higher percentage of results attained will be either indeterminate, hallucinatory, or unexpected. The machine, pushed to capacity in its attempts to utilize and integrate all available data in attempting to at least approximate our set goals, will be pushed to utilize all pertinent (and even non-pertinent) data. Bi-directionally, such machine dreams will be incorporated into the dream consciousness of interacting humans.

While we are not consciously attempting to extend computer capacity for attaining dream-like mentation, complex machine systems are incorporating active sleep modes, alternative logics, non-parametric programming, and extended interfaces into their processing capabilities. These approaches are being utilized in an effort to extend their capacity for human interaction and function into common-sense human interactions. In that somewhat illogical environment, modern AI systems are required to approach their external environment in similar ways to those used by humans. To function in that environment, even artificial systems will require the capacity to dream.

KEY TERMS AND DEFINITIONS

Anthropomorphic: Ascribing human forms or attributes to a being or thing not human, especially to a deity.

Artificial Intelligence: A computer system with capacities for self-learning.

Consciousness (AI Definition): The ability to rise above programming.

Ethics: A system of moral principles.

Metaphor: A term or phrase used to represent something else.

Singularity: The point at which a computer system will attain and move on beyond human capabilities.

INTRODUCTION

Whenever human observe a scene from a video, objects in scene despite being static keep on changing or moving rapidly with in a snapshot of time. Under such circumstances, detecting and tracking of objects in a scene is absolutely essential. However, active research has been progressing in this specialized field for the last three decades and as a result several algorithms have evolved for object detection and tracking. A robust, accurate and high performance approach is still a great challenge today. The difficulty level of this problem highly depends on how the object to be detected is defined and tracked. For a critical evaluation, frame differencing algorithm is chosen for object detection and Kalman filter is chosen for object tracking. Kalman filter algorithm is successfully implemented for tracking single objects with and without occlusions. In each case, tracking efficiency is determined with error covariance estimation. It is found that as error covariance tends to zero and goes to negative, the covariance of the predicted state becomes low and uncertainty is reduced. It is proved that Kalman filter is the best estimator and subsequently the experimentation is extended to multiple objects without occlusions and successful results are revealed.

BACKGROUND

The active research on object detection is going on for past few decades. The general approach for object detection is background subtraction, also known as foreground detection. Background subtraction is a challenging task, especially in complex dynamic scenes that might contain moving trees, rippling water, etc. Many approaches are presented in literature to deal with background subtraction (Elgammal 2014; Bouwmans 2011; Brutzer et al., 2011; Bouwmans et al., 2008). Huapeng Yua et al. (2014) proposed object detection using contour level top down information. Recently Kooij et al. (2015) proposed a novel approach for multiple object detection using their appearance. It identifies the minimal set of objects from a frame, from which the features are extracted. It focuses mainly on appearance rather than temporal cues. In tracking by detection method, target objects are detected and these are combined with consistent tracks. For example, human detectors can be trained on Histogram of Gradient (HoG) features or by analyzing about spatial occupancy to explain background/foreground masks (Ben Shitrit et al., 2011; Fleuret et al., 2008; Liem and Gavrilu, 2011). In terms of tracking, online trackers on a frame by frame basis can be differentiated (Breitenstein et al., 2011; Kim et al., 2012; Yan et al., 2012).

Procedure CECR (video)

```

while (end of video) do
    // stage 1: pre processing
    // two successive frames (i, i+1) are reading
        read (frame i)
        read (frame i+1)
    // frame i, i+1 are converted to gray
        grayframe1 = color2gray(frame i)
        grayframe2 = color2gray(frame i+1)
    // absolute difference is calculated
        absdiff_frame = absdiff(grayframe1,grayframe2)
    // gray threshold technique is applied
        binary_frame = threshold(absdiff_frame)
        normalized_box_filter(binary_frame)
        binary_frame = threshold(binary_frame)
    // stage2: Segmentation using Contour Extraction
    // (Suzuki 85)
        contours = getContours(binary_frame)
        no_of_contours = size(contours)
        drawAllContours(contours, contours_frame)
        centroid[i]= findCentroid(threshold_frame)
        generateTrajectory(centroid)
    end while
end CECR

```

OBJECT TRACKING USING CONTOUR EXTRACTION AND CENTROID REPRESENTATION

A primitive experiment is conducted on single object moving with a constant speed and no occlusions. In this perspective a series of videos captured using Nikon COOLPIX 12.0 mega pixels are used for motion analysis. For moving object identification, frame differencing technique is chosen. In this technique, absolute difference between two successive frames i and $i+1$ is calculated. For each of the differenced image that is obtained in each of the successive iteration, a grey threshold is calculated and is applied. As a result the differenced images are transformed into binary images. To smooth the binary image, normalized box filter is applied and then again grey threshold is calculated. As a result, the perfect binary image

is produced. For each of the moving object that is identified in the preprocessed image, a centroid is computed. This centroid represents the moving object in each of the differenced image. Finally a trajectory is drawn by connecting the centroids for all the differenced images. The results obtained after testing the algorithm in a video is presented for discussion. The pseudo code for object detection and tracking using Contour Extraction and Centroid Representation (CECR) is shown below.

In the preprocessing stage, two consecutive frames, say frame i and frame $i+1$, are read from the video. These frames are converted into gray format (grayframe1, grayframe2). The absolute difference is calculated between grayframe1 and grayframe2 and result is stored in absdiff_frame. absdiff_frame is converted into binary format using gray thresholding technique and result is stored in binary_frame. It is smoothed using normal-

Procedure *CECR_Kalman* (video)

1. Find foreground objects using CECR algorithm.
2. Kalman Filter object is Created with initial detected location (centroid value of initial frame).
3. The tracks are initialized. (track contains centroid, bounding box, id, age, kalman filter and total visible count).
4. New locations of existing tracks are predicted.
5. Update track details based on the new detections.
6. Delete the last tracks and create new tracks for next frame.

Procedure *PredictNewLocation* (initial track)

Covariance of predicted state vector (psv) $=A*P*A'+Q$

Where

A: State transformation matrix

P: State covariance matrix

Q: System noise

Kalman gain matrix (K)

$$K = psv * H^T * (H P H^T + R(t_i))^{-1}$$

where H- observation matrix

R-measurement noise

correction factor $\Delta(x_i)$

$$\Delta x(t_i) = K(t_i) \cdot (l(t_i) - (t_i)), \quad // \text{ measurement residual}$$

$$x^+(t_i) = x^-(t_i) + \Delta x(t_i)$$

$$\text{Error covariance } \Delta P(t_i) = E[\Delta x(t_i) \Delta x(t_i)^T]$$

ized box filter and then again gray thresholding is applied to get final threshold frame in binary format. The preprocessing result on a video from KTH data set (Schüldt et al., 2004) is shown in Figure 2. We have used OpenCV implementation (OpenCV 2.4.10) of contour extraction algorithm based on (Suzuki 85) to segment the binary frame. This generates a collection of external contours.

EXTENDED CECR USING KALMAN FILTER

We have extended the CECR algorithm using Kalman filter and it is shown below. The Kalman filter is a recursive estimator. It not only estimates the

state from the previous time step and the current measurement is needed to compute the estimate for the current state.

As explained presented above, foreground objects are detected using CECR algorithm and the motion of each track is estimated using CECR Kalman Algorithm. For motion analysis, a foreground object is represented as centroid and is used as a measurement for tracking. In order to predict the new location of the existing track, state vector $x(t_i)$, covariance matrix $(P(t))$, Kalman gain(K) and correction factor is calculated. Based on the new locations error covariance is estimated and then track details are updated. The algorithms for *PredictNewLocation* and *UpdateTrackDetails* are:

Figure 1. Sample images from KTH dataset a) Walking b) Jogging c) Running d) Boxing

Figure 2. Preprocessing result of CECR (video from KTH dataset) a) i th frame b) $i+1$ th frame c) Difference image d) Threshold image e) Blurred image f) final threshold image

Figure 3. Detection results of CECR a) video frame from KTH b) Video frame captured using Smart Phone

SOLUTIONS AND RECOMMENDATIONS

To study the performance of the proposed algorithm, experiments are conducted on KTH data-

set. Furthermore, experiments are conducted on various video sequences captured using Samsung Galaxy S3 smart phone.

Procedure *UpdateTrackDetails* (*ppre*, ΔP)

Updated covariance of the predicted state *p*

$$p(t_i) == ppre(t_i) + \Delta P(t_i)$$

$$\text{where } \Delta P(t_i) = (1 - K(t_i)) * H * ppre(t_i)$$

H is an observation matrix

(a)

(b)

(c)

KTH Dataset

It contains videos of six action classes (walking, jogging, running, boxing, hand waving, and hand clapping). Some of the sample frames are shown in Figure 1.

Multiple Object Tracking Results (Using CECR_Kalman)

To evaluate the performance of the proposed algorithm, experimentation is conducted on various scenarios as shown below.

In the above all scenarios, the graph between the frame and error covariance is drawn as shown in Figure 5 and the graph between the error covariance and covariance of predicted state is drawn as shown in Figure 6.

Variation of error covariance ΔP over a sequence of frames is depicted in the above Figure 5. The results show that ΔP is approximating to zero from the negative. It is interpreted from the above graph as the ΔP approaches to zero, covariance of predicted state (*P*) becomes low and hence the uncertainty will be reduced.

FUTURE RESEARCH DIRECTIONS

The work is likely to be extended for tracking of moving objects in non-stationary environment in case of partial and/or full occlusions, illumination changes and also in cluttered background. There is a possibility of extending the work in identifying and tracking the location of stationary and moving objects in 2D /3D space based on acoustic waves and visual ability i.e. with complex interaction of light, eyes and brain.

CONCLUSION

In order to study in depth the essence of existing target tracking algorithms developed based on their mathematical and environment of their applications, complex situations like partial and full

KEY TERMS AND DEFINITIONS

Binary Image: An image whose pixels have only two possible intensity values. They are normally displayed as black and white.

Correction Step: Uses the current value of the estimate to refine the result given by the predictor step.

Covariance Measure: Covariance measures the degree to which two variables change or vary together (i.e. co-vary).

Error Covariance Matrix (ΔP): Defines the expectation of the square of the deviation of the state vector estimate from the true value of the state vector.

Grayscale Images (or Gray Level): Are simply whose colors are the shades of gray. Each pixel in a gray scale image is represented only with single intensity value (stored as 8 bit integer value).

Image Filtering: It is the process of transforming pixel intensity values to reveal certain image characteristics like image enhancement, smoothing technique and template matching.

Kalman Filter: A recursive predictive filter used for estimating Kalman filter is used to estimate the state of a linear system where the state is assumed to be distributed by a Gaussian.

Kalman Gain Matrix (K): Determine the weighting of the measurement information in updating the state estimates.

Measurement Noise (R): Associated with the measurement vector, describes the statistics of the noise on the measurements.

Measurement Residue: Gives difference in measurement between the true state vector and the estimated state vector.

Measurement Vector: It is a set of simultaneous measurements of properties of the system which are functions of the state vector.

Object Detection: Identifying an object over a sequence of frames in a video.

Object Representation: In a tracking scenario, an object can be defined as anything that is of interest for further analysis.

Object Tracking: It is defined as the problem of estimating the trajectory of an object in an image plane as it moves around a scene.

Observation Matrix: It is a measure of how dependent the measurements are upon the state of the system.

Posterior State: State during time span (t_{i+1} to t).

Prediction Step: Calculates the next estimate of the state based only on past measurements of the output.

Prior State: State during time span (t_{i-1} to t).

State Transformation Matrix (A): It is an approximation of the change that the state undergoes over the specified time interval.

State Vector: Set of parameters describing a system, known as states, which the Kalman filter estimates.

System Noise (Q): Determines the variation in the true values of the states.

Thresholding: Separates the regions of the image corresponding to objects in which we are interested, from the regions of the image that correspond to background.

Semantic Intelligence

Maria K. Koleva

Institute of Catalysis, Bulgarian Academy of Sciences, Bulgaria

INTRODUCTION

Semantic intelligence is an exclusive for the intelligent complex systems way of response to non-specified and non-predetermined ever-changing environment subject to the mild assumption of boundedness alone. Its major distinctive property is autonomous comprehension and creation of information. Another exclusive property of semantic intelligence is autonomous discrimination between true and false statements.

The semantic intelligence naturally arises in the setting of concept of boundedness where it commences from highly non-trivial interplay between structural and functional properties of a complex system. The major generic property of that interplay is that it renders the relation between structural and functional properties to be non-recursive. In result this renders the efficiency of semantic intelligence to be provided by efficiency of hierarchical self-organization of a complex system prior to the efficiency of software and to the speed of hardware.

Concept of boundedness is a new explanatory paradigm aimed towards explanation of the behavior of the complex systems behavior. A systematic study can be found in (Koleva, 2013; Koleva, 2016). In the setting of this paradigm the semantic intelligence is implemented by a specific for each intelligent complex system hierarchical self-organization of the physical processes. The major generic property of this hierarchy extensively discussed in the chapter, renders it bi-directional and non-extensive.

The concept of boundedness is the first systematic theory which considers the behavior of complex systems in non-specified non-predetermined

ever-changing environment subject to the mild assumption of boundedness alone. The major assumption is that a non-predetermined bounded environment is the starting point for fundamentally novel properties of complex systems behavior, semantic intelligence included, which are not available for the traditional scientific approach where the environment is supposed set apriori. It is should be stressed that the traditional approach is grounded on the assumption that the environment is statistically or deterministically pre-determined and unbounded and hence all physical, chemical, biological and engineered systems are considered as set in specific pre-determined environment. The fundamental discrimination between both approaches consists of the fact that the behavior of corresponding systems, semantic intelligence included, is describable by non-recursive means while the behavior of the algorithmic intelligence is describable by recursive means only.

The goal of this chapter is to highlight the major properties of semantic intelligence that naturally arise under the concept of boundedness and to demonstrate their relation to the general characteristics of physical processes which implement it. This defines the strategic goal to be establishing the grounding principles of next generation approach for building a circuit able to exhibit semantic intelligence.

Since the semantic intelligence naturally arises in the frame of concept of boundedness, the most general assumptions of the concept of boundedness are presented. The necessary conditions for setting semantic intelligence are presented later. This is made because the intelligent complex systems are a sub-class of the family of complex systems. As such they share all properties of the wider class

of complex systems along with specific for the semantic intelligence properties. A comparison between the exclusive properties of semantic and algorithmic intelligence is made.

BACKGROUND

Before presenting the basic principles of the concept of boundedness let us remind the notion of a complex system and the major characteristics of their behavior. Let us start with the notion of a complex system: it is how parts of a system are organized so that the system behaves as a single object and how it interacts with its environment. Thus the notion of a complex system encompasses an enormous variety of systems ranging from physical ones such as quasar pulsations, to biological such as DNA sequences, to social ones such as financial time series.

The intensive empirical examination that was going on in the last decades displays the remarkable enigma of complex systems behavior: the highly specific for each complex system properties persistently coexist with certain universal, shared by each of them ones. Thus on the one hand, they all share the same characteristics such as power law distribution and sensitivity to environmental variations, for example; on the other hand, each system has its unique “face”, i.e. one can distinguish between an earthquake and heartbeat of a mammal. What makes the study of this coexistence so important is the enormous diversity of systems where it has been established. In order to get an idea about this vast ubiquity let us present a brief list of such phenomena: earthquakes, traffic noise, heartbeat of mammals, public opinion, currency exchange rate, electrical current, chemical reactions, weather, ant colonies, DNA sequences, telecommunications, etc.

But the greatest mystery enshrined in the behavior of complex systems is that both intelligent and non-intelligent systems belong to the same class: thus a Beethoven symphony, a product of a genius mind, and the traffic noise which,

though being also a product of human activity, but un-intelligent in its behavior, share the same type of power spectrum. Another example is the semantics of human languages: in the year 1935 the linguist G. K. Zipf established that, given some corpus of natural languages, the frequency of any word is inversely proportional to its rank in the frequency table. Thus the most frequent word will occur approximately twice often as the second most frequent word, three times as often as the third most frequent word, etc. Thus, the Zipf law ignores any semantic meaning and thus it seems to sweep out the difference between mind activity and random sequences of letters. Thus we come to the following fundamental problem: what makes a complex system “intelligent” and why it should share such “indifferent” to the intelligence properties?

The affiliation of the apparently intelligent systems such as human languages and music to the same class as earthquakes and a variety of other natural phenomena, suggests in a straightforward way that the intelligent behavior is embedded in natural processes. Thus the opposition between intelligence as highly specific activity and the fact that it inherently belongs to a universal class of natural phenomena raises the major question whether it is likely to expect defining a criterion able to distinguish the specificity of a system from another one along with affiliating each of them to the same class of complex systems.

CONCEPT OF BOUNDEDNESS – GENERAL PRINCIPLES

Next the grounding assumptions of the concept of boundedness are introduced. They are:

- A complex system remains stable if and only if the rate and amplitude of variations that it exerts in response to an ever-changing environment are bounded to specific for the system margins.

- The response is local and not pre-determined. This implies that it depends on the current state of a system and the current environment impact. Yet, in order to sustain boundedness of rates it behaves in a non-linear and non-homogeneous way.
- Complex systems are self-organized in a hierarchy of responses so that different hierarchical levels are linked through inter-level feedbacks. An exclusive property of the inter-level feedbacks is that each of them operates as a bounded irregular environment for the self-organization at each and every hierarchical level. In turn this provides bi-directionality of the hierarchy as it goes both bottoms up and top down. This is in sharp contrast with the traditional approach where different objects are considered closed systems and the hierarchy goes only bottom up.

A central for the boundedness result is the proof that there exists a presentation basis where the response decomposes into two parts, specific and universal one, each of which has characteristics that are robust to environmental variations. The rigorous assertion is that the power spectrum of each time series that represents the behavior of a complex system is decomposable into two parts: a specific discrete band and a continuous band whose shape is universal. Further, the claim is that the decomposition is additive and it happens with constant in the time accuracy.

In addition to these two parts in the power spectrum a non-recursive component persists at finite distance from both of them. It commences from the highly non-trivial interplay between the specific and the universal part. Since each time series which represents a record of the behavior of a complex system is bounded irregular sequence, it could be presented as wild and permanent bounded “twisting” and “winding up” around a “skeleton” built on the discrete band of the power spectrum. Thus, the motion resembles the mo-

tion on a torus with irrational frequencies. In the present case the motion never stops and thus the extra-line associated with irregular motion around the skeleton appears always as non-recursive regardless to the relations among the thresholds over the corresponding and the other scales in the corresponding system.

It should be stressed on the fact that non-recursive component persists only for bounded variations since, if variations are unbounded, the non-recursive component is shifted away to the infinity at the left of a power spectrum. Thus, the boundedness turns out to be the crucial factor in setting the non-recursivity of relation structure-functionality which in turn serves as the major distinctive implement for semantic intelligence. As consequence, the semantic intelligence turns out to be an exclusive for the concept of boundedness way of response to an ever-changing environment.

The greatest value of that decomposition is:

1. It allows unambiguous separation of an object from its environment. The notion of an object consists of specific pattern, called homeostasis, because its characteristics remain intact in an ever-changing environment. Moreover, one can define them regardless to the details of that environment.
2. Although the exact local behavior remains unpredictable, it provides predictability of the behavior of each complex system up to the predictability of its current homeostatic pattern.
3. The persistence presence of a non-recursive component constitutes the non-recursive way of relating structural and functional properties. Indeed, while structural properties are defined through the specific pattern whose power spectrum is given by the discrete band, the functional properties are presented through the entire power spectrum, i.e. through the interplay among specific, noise and non-recursive component altogether.

SEMANTIC INTELLIGENCE AS A SUB-CLASS OF COMPLEX SYSTEM BEHAVIOR

Next the necessary conditions for the realization of the semantic intelligence are considered. It should be stressed that the class of intelligent complex systems is a sub-class of complex systems. Thus, all complex systems are subject to boundedness but the intelligent complex systems are subjected to an additional constraint which will be presented next.

An exclusive property of any complex system considered in the frame of boundedness is that its state space is partitioned into domains so that each domain is characterized by a specific for it homeostatic pattern; the rate of intra-domain motion is bounded and irregular. In result the motion among domains is restricted to the adjacent domains only. The boundedness of the inter-domain motion renders the state space trajectories to be non-random. This is so because any trajectory in a state space goes in such a way that it jumps only to adjacent states. The allowed inter-domain motion is confined only to the adjacent domains next to any given domain. The selection of any of the adjacent domains is random one since in each run it depends on the current intra-domain trajectory which is irregular.

The general necessary constraint which provides implementation of the semantic intelligence by physical processes consists of requirement that the state space of any intelligent complex system is to be partitioned into at least 4 domains. The reason behind the particular choice of no less than 4 domains will become clear later.

The utilization of this constraint is two-fold:

- The first assumption is to associate information symbols with intra-domain homeostatic patterns. The far-going consequence of that association consists of providing algorithmic uniqueness of each and every specific law. The algorithmic uniqueness is achieved through the ubiquitous presence of a non-recursive component additional to the homeostatic and noise characteris-

tics. To remind, a “non-recursive” implies that neither specific law can be achieved by finite number of steps organized in an algorithm. The non-recursive component comes from a highly non-trivial interplay between the homeostatic pattern and inter-level feedbacks for every intelligent complex system as explained in the previous section. In turn it makes different specific laws unique and algorithmically unreachable from one another. It should be stressed that the comparison with the traditional explanatory paradigm displays a sharp contrast. Indeed, the traditional explanatory approach assumes existence of a universal law such that all specific laws are its algorithmic derivatives.

- The second assumption consists of association of the meaning of each semantic unit with the performance of a specific non-mechanical engine built on the corresponding inter-domain orbit in the state space. As an example of non-mechanical engines may be considered the bio-chemical cycles in living organisms. The exclusive property of presentation of the meaning of a semantic unit through performance of an engine is that the latter provides sensitivity to permutations of the semantics. Indeed, like the semantics of human languages where the meaning of each word depends on the order of the letters in it, an engine performs differently if it operates in different directions. Thus, for example the famous Carnot engine operates in one direction as a pump and in the opposite direction it performs as refrigerator.

Thus, each semantic response consists of hierarchy of cycles which follow through adjacent states only irrespectively to the intensity of the current environmental impact. In turn, this provides the most fundamental property of the semantic intelligence to be the autonomous creation and comprehension of information.

Thus, there are two ways of presenting a semantic unit: the first one is through the sequence of information symbols which it consists of while the second one is through performance of a specific engine. This two-fold presentation of every semantic unit is the major implement for non-extensivity and bi-directionality of the hierarchy of every semantic response. It should be stressed that both presentations are algorithmically unreachable from one another.

SECOND LAW AND SEMANTIC INTELLIGENCE

The next point is the relation between physical processes which implement semantic intelligence and their environment. The importance of this question is rendered by the fact that in the traditional algorithmic approach no hardware is in balance with its environment. This is so because it is assumed that any hardware can execute any algorithm. In turn this opens the door to an uncontrolled “drainage” of the environment or its uncontrolled heating. Thus a question arises: can one built information perpetuum mobile? The answer is negative and it consists of reformulation of the Second Law so that its availability to encompass the widest scope of systems.

A clue for the most general formulation of the Second Law in the frame of boundedness is the need for its availability to semantic intelligence. Since the latter is executed by means of performance of non-mechanical engines, an appropriate formulation should be grounded on their generic properties. The author have proved that under boundedness the efficiency of a non-mechanical engine never exceeds the efficiency of corresponding Carnot engine where the engine is free from necessity of a physical coupling to two heat reservoirs. Alongside, the proof is free from the condition for entropy maximization viewed as condition for reaching equilibrium. Thus the proof substantiates the most ubiquitous

formulation of the Second Law to impose ban over perpetuum mobile.

It should be stressed that the present formulation of the Second Law justifies the general condition about the necessity of at least 4 domains with different homeostasis for implementation of semantic intelligence. Indeed, suppose that a cycle consists of a trajectory that goes through 3 domains only. Then the corresponding engine performs all possible permutations in a single cycle by means of running it in opposite directions and starting at different states. Thus the words ‘dog’ and ‘god’ and words ‘on’ and ‘no’ are product of the same engine but run in opposite direction. Therefore, it is obvious that only orbits which go through at least 4 states provide different cycles for different permutations. Further, the work produced by different engines is a measure for the efforts exerted behind any semantics. Since the engines are specific, the corresponding work is also specific for each semantic response. In turn this puts the hierarchical organization of the semantic response prior to the fact whether it is fastest or most efficient. This fact is opposite to the traditional algorithmic approach where the fastest computers and the most efficient algorithms are most valued.

It is worth noting the sharp contrast with the traditional approach. A generic property of the state space in the traditional approach is the Markovianity. It implies that successive jumps are not correlated and the trajectories never close. As a result no semantic intelligence is ever possible in the frame of the traditional approach.

The most fundamental property of the semantic intelligence, the autonomous creation and comprehension of information comes at a price: unlike a Turing machine which is able to execute every algorithm, the semantic intelligence executes only algorithms compatible with its “hardware”. However, this is rather an advantage than a setback because it serves as grounds for autonomous discrimination of a true and a false statement by semantic intelligence.

Then, the distinctive properties of both algorithmic approach and semantic intelligence make them rather counterparts than opponents.

Summarizing, the additional constraint to which intelligent complex systems are subject is that its state space must consist of at least 4 domains. This condition is satisfied for spatially heterogeneous systems only. The state space of homogeneous systems has only 2 domains. Put in other words, only systems which are self-organized in patterns or are subject to morphogenesis can exhibit semantic intelligence. Yet, at this point a question arises: the necessary condition for heterogeneity is to have 3 domains in the state space. Then, to what generic type of pattern formation the requirement of about at least 4 domains corresponds?!

A great advantage of the semantic intelligence is that it is in balance with the environment. This fact is an immediate consequence of the assumption about considering semantic intelligence as a sub-class of complex systems. Then any piece of semantics is executed as a sequence of information symbols. A generic property of this sequence is that, being a bounded irregular sequence, its variance is always finite (Koleva, 2013).

MAJOR DIFFERENCES BETWEEN SEMANTIC AND ALGORITHMIC INTELLIGENCE

Algorithmic intelligence is grounded on the rules of formal logic. It is widespread since it serves as grounds for the software of all computers. It is worth noting that the formal logic presupposes execution of any algorithm by recursive means only. Alongside, the compatibility between software and hardware implies that the latter operates by means of linear processes only. In turn, this provides the most exclusive for the algorithmic intelligence property, which is the property that any algorithm can be executed by any hardware. However, this property comes at a price which is

best seen through the differences with the semantic intelligence. Next the major of them come:

- Algorithmic intelligence is not able to create or comprehend any information in an autonomous way; semantic intelligence comprehends and creates information in an autonomous way. Algorithmic intelligence can execute any algorithm by any hardware because the relation software-hardware is expressed by recursive means only. On the contrary, the non-recursive relations between structural and functional properties of intelligent complex systems render a specific compatibility between software and hardware.
- Algorithmic intelligence assumes acquiring of absolute knowledge about each system by means of obtaining definite answers to yes-no questions through cleverly posed experiments. This assumption is grounded on the idea that relation impact-response is always recursive. On the contrary, the setting of boundedness puts at the center preservation of the current homeostasis. A central for the boundedness property is that the response of each complex system decomposes into a specific and universal part whose properties are robust to environmental changes. The specific information about any system is concentrated into the specific part called homeostasis. Then, any specific knowledge about a system comes at the expense of presence of accompanying noise whose intensity cannot be made arbitrarily small. In turn, this makes obtaining of absolute knowledge impossible.
- Algorithmic intelligence assumes generation of information out of noise processes. On the contrary semantic intelligence puts a ban over creating information out of noise. The semantic intelligence can be executed only by means of going through changes into homeostasis. Thus the meaning of a semantic unit is performed as a

non-mechanical engine whose working cycle goes through at least 4 states of different homeostasis. Then, it is obvious that acquiring information out of noise alone is impossible. This setting is in sharp contrast with the traditional algorithmic approach where it is assumed possible to obtain information from noise.

- Algorithmic intelligence assumes that the only relation between a semantic meaning and the sequence of symbols that constitutes it is expressed by recursive means only. In turn this justifies the major goal of algorithmic theory to be search for fastest computer and most efficient algorithms. A crucial notion of the concept of boundedness is the implementation of semantic meaning through performance of a non-mechanical engine. It is important to stress that it utilizes the fact that the latter is algorithmically irreducible to the sequence of symbols that constitute it. In turn this renders the leading role of hierarchical super-structuring of intelligent complex systems prior to the efficiency of software and the speed of the hardware.
- An important consequence of the presentation of semantic intelligence as a sequence of semantic units is that renders possible autonomous comprehension of true and false statements. A 'true' statement corresponds to that unique trajectory, which has been physically realized in a given run; a 'false' statement is the one that follows an imaginary trajectory that comprises a non-admissible state; a counterfactual corresponds to an admissible trajectory which has not been realized in a given run. And last but not least, an improbable statement corresponds to an imaginary impasse: the statement does not correspond to any trajectory. Thus, the automatic selection of trajectories to admissible and non-admissible renders the fundamental difference of the present approach from the traditional

algorithmic theory and the formal logic which are grounded on the assumption that all trajectories are available. Let us provide an example: the sentences "the Sun rises at east" and "the Sun rises at west" are both true in the setting of algorithmic theory because they are both grammatically correct; on the other hand in the setting of boundedness the first sentence "the Sun rises at east" is true since it corresponds to a physically realizable trajectory while the sentence "the Sun rises at west" is false because it corresponds to a physically unrealizable trajectory.

FUTURE RESEARCH DIRECTIONS

The semantic intelligence puts a bridge over physics, biology and artificial intelligence. As a corollary of the development of this novel theoretical framework one of the major directions in the future research is establishing the principles of the next generation strategy aimed towards building of a circuit capable to autonomous comprehension and creation of information. One of the key questions about this strategy is whether such circuits are capable to evolution.

The grounds for such question come from the exclusive for the theory of boundedness property that is the non-recursive relation between structure and functionality which thus serves as major implement for novel route to evolution different from the survival of the fittest. The non-recursive relation between structure and functionality sets the major advantage of that route to evolution to be the best hierarchical organization irrespectively whether is the fastest or the least energy consuming because its exclusive property is that it is in balance with its environment. And since this hierarchy is bi-directional, it acts as specific promotor to evolution: only compatible with the entire hierarchy changes are allowed. On the contrary, the traditional assumption about recursive relation between structural and functional prop-

erties implies that the only route to evolution is survival of the fittest: the best construction provide the best performance.

Thus, in the frame of the theory of boundedness it is to be expected appearing of the two routes to evolution as counterparts rather than as opponents. The question that stands now is how to utilize in the best way the interplay between both routes to evolution for achieving sustainable development of artificially created circuits operating by means of semantic intelligence?

CONCLUSION

The properties of semantic intelligence, viewed as an exclusive for intelligent complex systems response to non-specified and non-predetermined ever-changing environment, are considered in the present paper. The semantic intelligence naturally arises in the frame of recently introduced concept of boundedness. An exclusive for the concept of boundedness property is that the relation between structural and functional properties of complex systems is non-recursive on the contrary to the traditional science where the relation between structural and functional properties is supposed recursive one. In turn, this renders the most efficient hierarchical organization to become more important for the functioning of a complex system than the efficiency of the software and the speed of the hardware. The best hierarchical organization provides multi-purpose usage of specific for every system relations between structure and functionality. The major difference with the traditional engineering is that the multi-purpose usage of this relation is subject to the following constraint: since the semantic intelligence is in balance with the environment, only compatible with the entire hierarchy changes are allowed. On the contrary, the recursive relations between structure and functionality render that the most effective structure automatically provides the best performance.

The non-recursive relation between structure and functionality serves as grounds for the most exclusive property of semantic intelligence, i.e. the ability for autonomous creation and comprehension of information. Another exclusive for the semantic intelligence property is that it automatically distinguishes between true and false statements. These properties provide major difference with Turing machines. Turing machines are able to execute any algorithm by means of any hardware but neither of them is able to autonomously comprehend the output and to distinguish whether the latter is true or false. On the contrary, the execution of semantic intelligence requires compatibility between software and hardware but the gain is autonomous comprehension of the output and autonomous distinguishability of its value, i.e. the semantic intelligence automatically distinguishes whether it is true or false. In turn, this makes semantic intelligence and Turing machines rather counterparts than opponents.

The systematic development of the properties of semantic intelligence in the frame of the concept of boundedness defines the strategic goal of the future research to be establishing the grounding principles of next generation approach for building a circuit able to exhibit semantic intelligence. One of the key questions about this strategy is whether such circuits are capable to evolution. The grounds for such question come from the exclusive for the theory of boundedness property that is the non-recursive relation between structure and functionality which thus serves as major implement for novel route to evolution different from the survival of the fittest. The non-recursive relation between structure and functionality sets the major advantage of that route to evolution to be the best hierarchical organization irrespectively whether is the fastest or the least energy consuming because its exclusive property is that it is in balance with its environment. And since this hierarchy is bi-directional, it acts as specific promotor to evolution: only compatible with the entire hierarchy changes are allowed. On the contrary, the traditional assumption about recursive

relation between structural and functional properties implies that the only route to evolution is survival of the fittest: the best construction provide the best performance.

Thus, in the frame of the theory of boundedness it is to be expected appearing of the two routes to evolution as counterparts rather than as opponents. The question that stands now is how to utilize in the best way the interplay between both routes to evolution for achieving sustainable development of artificially created circuits operating by means of semantic intelligence?

KEY TERMS AND DEFINITIONS

Algorithmic Intelligence: Exclusive for the formal logic way of “response” to an input.

Concept of Boundedness: A new explanatory paradigm, put forward by the author, aimed towards explanation of the behavior of the complex systems behavior.

Non-Recursive Relation: Relation that cannot be expressed in a closed form or by means of finite step algorithms.

Second Law: One of the most fundamental laws in physics.

Semantic Intelligence: Semantic intelligence is an exclusive for the intelligent complex systems way of response to non-predetermined and non-specified ever-changing environment. Its major distinctive property is autonomous comprehension and creation of information. Another exclusive property of semantic intelligence is autonomous discrimination between true and false statements.

Survival of the Fittest: A theory of evolution grounded on the assumption that for any given change in the environment the best suited structure of an object provides the greatest advantage in performance. This assumption is explicit outcome of the assumption that the relations between structure and functionality are expressed by recursive means only.

The Summers and Winters of Artificial Intelligence

Tad Gonsalves

Sophia University, Japan

INTRODUCTION

Humanity has toyed with the idea of building intelligent machines from antiquity. The ancient Egyptians, Greeks, and the Chinese are reported to have built mechanical devices that imitated human intelligence, although primitively. In the 16th century, it was Hobbes who stated that thinking was symbolic reasoning like working out an answer with pen and paper. This idea of thinking as symbolic reasoning was further developed by Descartes, Pascal, Spinoza, and Leibniz (Poole & Mackworth, 2010). The English mathematician Charles Babbage, who designed the Analytical Engine in 1837, is considered to be the inventor of the modern computers. Although the Analytical Engine was not built until 1991, it served as a prototype of the modern general-purpose computer. The first link to machines and intelligence is found in the 1950 paper published by Alan Turing, “Computing Machinery and Intelligence” (Turing, 1950). The “Turing test” proposed in this paper, is a simple pragmatic approach assuming that a computer that is indistinguishable from an intelligent human actually shows that machines can think. Its relevance to this day seems to indicate that it will be a goal for the AI field for many years to come (McGuire, 2006).

The term “Artificial Intelligence” was coined by John McCarthy in a conference organized in 1956 in Dartmouth (McCarthy, 1955). He defines *intelligence* as the computational part of the ability to achieve goals in the world and *Artificial Intelligence* (AI) as the science and engineering of making intelligent machines, especially intelligent computer programs (McCarthy, 2001).

AI has had a tumultuous history (McCorduck, 1979; Crevier, 1993). The early theorem proving and checkers playing programs astonished the public with their seemingly intelligent performance. The expert systems, too, drew great admiration from the general public as well as the specialists, since their competence and performance in consultation was in par with human experts. This chapter introduces DENDRAL and MYCIN, two of the most successful expert systems developed in the childhood of AI.

However, the hype and expectations raised by these early systems led to the downfall of AI in the ensuing years. Perceptrons, for example, were just picking up as promising machine learning mechanisms when they were nipped in the bud by other AI researchers owing to a premature evaluation. Their apparent inability in evaluating the XOR and the NXOR functions was later rectified by the introduction of an additional middle layer of neurons. However, this came much later, and enough harm had already been done to the Artificial Neural Network research.

The ALPAC report in 1966 and the Lighthill report in 1973 were responsible for the onset of an all-time low-fund and low-activity period, called the AI winter. The two fatal reports not only led to the cutting of funds, but a general distrust in AI research. The recent victories of AI programs over human champions in chess and in Jeopardy have restored faith in AI discipline. AI has run its course through summers and long winters. True, we are far from an overall theory or framework, explaining what thinking is and how to build intelligent machines (Lungarella, 2007). Nevertheless, AI has made great strides and, after overcoming

Figure 1. The AI hype curve

the *trough of disillusionment* is marching on the *plateau of productivity*.

BACKGROUND

As it happens to any new technology, the history of AI, too, ran through a hype curve (Menzies, 2003). The early AI programs like the ones elegantly proving theorems and skillfully playing board games aroused great interest and expectations. This was followed by the successful application of Expert Systems in business and academia. This early period in the development of AI is referred to as the “peak of inflated expectations” shown in the AI hype curve (Figure 1).

However, for the next ten years AI did not live up to its expectations. Not getting any substantial returns, the AI investors and stakeholders appointed special committees to inquire in the progress of AI. This period called the “trough of disillusionment” proved fatal to the development of AI. The summers and the winters experienced in the history of AI are tersely expressed in the words of Tim Menzies (Menzies, 2003):

In the 21st century, AI has many reasons to be proud, but it wasn't always this way. New technologies such as AI typically follow the hype curve. By the mid-1980s, early successes with expert systems caused skyrocketing attendance at AI conferences and a huge boom in North American AI startups.

Just like the dot-coms in the late 1990s, this AI boom was characterized by unrealistic expectations. When the boom went bust, the field fell into a trough of disillusionment that Americans call the AI Winter. A similar disillusionment had already struck earlier, elsewhere.

The funds were heavily cut and AI research almost came to a grinding halt. Despite the setbacks, some AI researchers persisted with their research in a few selected areas, refraining from calling their work “AI”. Their approach finally led to the “slope of enlightenment” bringing AI out of the harsh winters. In the 1990s AI research began to flower again culminating in the victory of IBM’s Deep Blue over the reigning chess world champion. Yet another milestone heralding the “plateau of productivity” was IBM’s Watson’s victory over the Jeopardy world champions in the year 2011.

THE HEY DAYS OF EXPERT SYSTEMS

An Expert System is a program designed to solve problems at a level comparable to that of a human expert in a given domain (Cooper, 1989). Also known as Knowledge-based system, an Expert System relies on the expert human knowledge captured in a computer program to solve problems that ordinarily require human expertise. It

has a vast store of knowledge in the knowledge-base and uses some kind of reasoning process to infer solutions to a given problem. The problems solved by an Expert System are restricted to their respective domain field. Accordingly, the Expert Systems do not display general intelligence like human beings, but can be immensely skillful in analyzing and solving problems in specialized domains (Duda, & Buchanan, 1982; Giarratano, & Riley, 1998; Nikolopoulos, 1997; Rajendra, & Sajja, 2010). Expert Systems do not use abstruse numerical reasoning. Rather, they follow human-like rules of thought, and can answer why and how questions reasonably well (Sashikumar, 2006; Schalkoff, 2011). This is because, in addition to the knowledge base and the inference module, they are also equipped with an explanation module.

The following sub-sections describe two of the highly successful Expert Systems, DENDRAL and MYCIN developed in the mid 60's.

DENDRAL

DENDRAL (acronym coined from DENDritic ALgorithm) was the earliest expert system developed in 1965 at Stanford University by a team of computer scientists, organic chemists and geneticist(s). It was a chemical-analysis expert system, programmed in LISP considered to be *the* AI language of that period (Boban, 2013). DENDRAL was designed to function in the domain of organic chemistry and mass spectrometry. The chemical substance to be analyzed had its spectrographic data fed into the system, and the system would hypothesize the substance's molecular structure (Lindsay et al., 1980). For example, the molecular weight of hydrogen and oxygen is 1 and 16, respectively. Therefore, the mass spectrum of a water molecule (H_2O) formed from two molecules of hydrogen and one molecule of oxygen has a peak at 18 units. DENDRAL would use this input mass and the knowledge of atomic mass numbers and valence rules, to determine the possible combinations of atomic constituents whose mass would add up to 18.

DENDRAL followed a typical plan-generate-test method to arrive at a solution to the given problem. The generator module would generate potential solutions for a particular problem, which were then expressed as chemical graphs. Faced with a large numbers of possible solutions, Dendral had to find a way to put constraints that would rule out many candidate solutions. This was the function of the planner module, which was a hypothesis-formation program. Finally, the tester module would analyze each proposed candidate solution and discarded those that failed to fulfill certain criteria (Lindsay et al., 1980).

DENDRAL was a convergence of three different technologies: knowledge engineering, machine learning and heuristics programming. A heuristic is a *rule of thumb* that human experts use intuitively in solving a problem. Heuristic programming models the expert heuristics in programming. In particular, they are used to introduce short-cuts to reduce the search through the huge knowledge base. Heuristics programming was a major approach and a giant step forward in Artificial Intelligence, as it allowed scientists to finally automate certain traits of human intelligence (Lindsay et al., 1980).

DENDRAL's performance rivaled that of a chemist expert at this task. However, this was not because the program knew more than an expert. It performed well because of its systematic search through the space of possibilities and its systematic use of what it knew. Although, it did receive a good coverage in chemical journals, its actual use in industry and academia was somewhat limited.

MYCIN

MYCIN, as the name suggest was an early medical expert system developed in the early 1970s at Stanford University (Buchanan & Shortliffe, 1984). MYCIN's main task was to diagnose infectious blood diseases and recommend antibiotics as a doctor in real-life would do. Although the inferences were based on a knowledge-base containing a modest 500 rules, MYCIN's success was

Table 1. XOR function

Input x_1	Input x_2	Output
0	0	0
0	1	1
1	0	1
1	1	0

impressive. Apart from diagnosing the bacterial infections and prescribing medication, it would also give an explanation and its reasoning procedure to the patient at the end, which increased its credibility.

A typical rule in MYCIN has an antecedent and a consequent. We refer to the antecedent of a rule as the premise or left-hand side (LHS) and to the consequent as the action or right-hand side (RHS). The inference can either take the forward chaining or the backward chaining mechanism. Forward chaining is also called data-directed inference, because the data that are known drive the inferences from left to right in rules, with rules chaining together to deduce a conclusion.

MYCIN primarily used backward chaining, or a goal-directed control strategy. The deductive validity of the argument is established in the same way, but the system's behavior is very different. In goal-directed reasoning a system starts with a statement of the goal to achieve and works backward through inference rules, i.e., from right to left, to find the data that establish that goal (Buchanan, & Shortliffe, 1984).

In several tests conducted by the Stanford medical school, MYCIN was found to perform better than the average physicians in diagnosis and prescription. However, due to legal and ethical issues it was never used commercially.

A BLOW TO CONNECTIONISM

The field of Artificial Neural Networks (ANN) is currently a budding field of AI. It is conventionally used as a de facto methodology in machine

Table 2. NXOR function

Input x_1	Input x_2	Output
0	0	1
0	1	0
1	0	0
1	1	1

learning and pattern recognition. Although the research in ANN began in 1940s, it had a severe setback in the late 60s. This section outlines the development of ANN and the cause of its decline in the late 60s.

Neurons modeled as binary threshold activation functions (McCulloch & Pitts, 1943) were successful in evaluating the basic logic gate functions. Rosenblatt further developed the basic neuron model and called it *perceptron* (Rosenblatt, 1962). The perceptron had weights assigned to the inputs and learning consisted in adjusting the connection weights to produce appropriate outputs. In the training phase, inputs are provided to the input layer of the perceptrons and the outputs are compared to the known outputs of the data-sets used for learning. The internal weights of the perceptrons are adjusted in iterative controlled steps until the error between the known output and that predicted by the perceptron is reduced below a desired level. This positive feedback enables the perceptrons to learn the patterns that map the input to the output. The perceptrons, in general, serve as linear threshold functions.

The perceptron, however, had some limitations. For example, it could not solve the exclusive OR function (XOR) (Table 1) and the exclusive NOR (NXOR) function (Table 2).

Minsky and Papert (1968, 1988) showed that the perceptron could only solve linearly separable functions and argued that the representations learned were inadequate for intelligent action. Their ill-timed remark led to the decline in the perceptron research until about the 1980's. Later researchers overcame the limitations of the Rosenblatt perceptron model by creating neural networks

with hidden layers. These networks connect the neurons of the input layer to those in the output layer via the neurons in the hidden layer. Learning involves adjusting all the connection weights given an input dataset with known output. Although the present day ANN have grown considerably more complex, they still stem from the early advances of the McCulloch-Pitts neuron and the Rosenblatt perceptron.

TWO FATAL REPORTS

Progress in science depends to a great extent not only on intellectual creativity but also financial support. It is widely known in the history of AI that it suffered drastic funding setback that led to its downfall. Two major reports were responsible for this downfall. The first was the ALPAC Report of 1960, the second the Lighthill Report some ten years later. The former was launched in the USA, and virtually stopped machine translation funding on both sides of the Atlantic. The latter originated in the UK and caused significant damage there – “with shock waves spreading across the Pond” (Boden, 2006).

The ALPAC Report

In the 1950s, the climate for machine translation was very favorable. Optimism reigned in the 1952 conference on machine translation. Many universities in the US, UK and Russia started major machine translation projects. At Georgetown University, in particular, devoted researchers began building a pilot system to convince potential funding agencies of the feasibility and the practicability of machine translation. This led in 1954 to the famous Georgetown experiment, a pilot system translating from Russian to English, which was hailed as an unqualified success - during the next ten years over 20 million dollars were invested in machine translation by various US government agencies (King, 1984).

As it happens in all new technology projects, there was an initial hype, but soon the AI researchers faced grand challenges in natural language processing and in machine translation (MT), in particular. In 1964, owing to the lack of appreciable results, the US government appointed a committee to evaluate the MT research. This “Automatic Language Processing Advisory Committee” (ALPAC), compiled a report in 1966 (Pierce, 1966) which proved fatal to MT researchers. The report stated that MT was slower, less accurate and twice as expensive as human translation and that there was no immediate or predictable prospect of useful machine translation. MT research funds were soon suspended and for years after that the message given to the general public was that MT was utterly hopeless (Hutchins, 1996; 2005).

The Lighthill Report

In 1973, the UK Science Research Council commissioned Sir James Lighthill, the FRS Lucasian Professor of Applied Mathematics, Cambridge University, to evaluate the state of AI research in the UK. The Lighthill report (Lighthill, 1973) stated straightforward that AI had simply not lived up to the expectations, calling all AI achievements as past disappointments.

The main section of the document was titled “Past disappointments”. Lighthill included an example of automatic landing system for airplanes, where conventional engineering techniques using radio waves had proven to be more useful than AI methods. Although AI techniques might be useful when landing an aircraft on an uncontrolled environment, Lighthill saw AI was nowhere near a practical solution. He also cited the lack of sophistication of chess programs that only reached an “experienced amateur” level at that time. Other than showing the lack of successful AI applications, Lighthill pointed out that all AI method required substantial knowledge of the subject matter in order to be useful. He was unsatisfied with at the lack of ability to automatically acquire knowledge that made the AI methods not really intelligent.

The problem of combinatorial explosion was specifically cited ridiculing the state-of-the-art AI technologies as merely applicable for solving toy problems in the laboratory and not scalable to the real world problems. Professor Lighthill, being an expert in fluid dynamics could not comprehend how a robot would function without the explicit coding of each and every instruction necessary for real-life behavior and action, since an infinite series of actions are not possible in the real-life situation. Thus, robotics was doomed to fail due to the combinatorial explosion problem. This same argument would apply that chess playing AI programs performing on the Grand Master level would be virtually impossible.

Lighthill's report provoked a massive loss of confidence in AI by the academic establishment in the UK including the funding body. It persisted for almost a decade.

TWO TRIUMPHS OF AI

In 1997, the IBM supercomputer Deep Blue defeated the chess world champion, Gary Kasparov. In 2011, the IBM supercomputer Watson, named after IBM's founder, defeated the reigning Jeopardy champions, Brad Rutter and Ken Jennings. Judging from these two major triumphs against human champions one might say that AI has recovered from the long winters and is making sustainable progress in the 21st century.

IBM's Deep Blue

In the 1997 chess world championship man-machine match, the first game was won by Kasparov and the second by Deep Blue; the next three games were a draw. In the 6th game, Deep Blue defeated Kasparov (Newborn, 2003).

Deep Blue's decided its moves by computing the evaluation function, which is a measure of the goodness of a given chess position. Deep Blue's evaluation function looked at four basic chess values: material, position, King safety, and tempo. Material is based on the worth of a

particular chess piece. For example, if a pawn is worth one point, a knight or bishop three, a rook five and the queen nine. However, conducting an exhaustive search to find the best possible move is next to impossible since the game of chess has a state-space of 10^{23} and game-tree complexity of 10^{143} (Iida, 2002).

However, instead of analyzing to the end of the game, the chess-playing program can merely look a few moves further ahead than a human could manage. Deep Blue typically looked 12 plies ahead in all variations (and 40 or more plies in selective lines), generating around 200 million nodes per second. It would evaluate each of these node positions and add points for a range of positional factors, chosen from a data-based created by human grandmasters. (Hsu, 1999; 2002)

Deep Blue conducted the search using a massively parallel, RS/6000 SP Thin P2SC-based system with 30 nodes, with each node containing a 120 MHz P2SC microprocessor, enhanced with 480 special purpose VLSI chess chips. Its chess playing program was written in C and ran under the AIX operating system. In June 1997, Deep Blue was the 259th most powerful supercomputer according to the TOP500 list, achieving 11.38 GFLOPS on the High-Performance LINPACK benchmark (Gelder, 1998).

IBM'S Watson

In 2011, IBM's supercomputer Watson, named after IBM's founder, defeated the reigning Jeopardy champions, Brad Rutter and Ken Jennings. Jeopardy is a well-known TV quiz in the US (Baker, 2012). Watson was designed to take the hints from the Quiz, do natural language processing and frame the Jeopardy questions. The following represents a typical Jeopardy question. "This NFL quarterback is a great-great-great-grandson of Brigham Young." Jeopardy question can be complex, usually requiring the contestant to put several facts together. Fortunately, for Watson, the answers were formatted very neatly. In this case, the answer is "Who is Steve Young". Watson simply had to return a fact (Heaton, 2011).

Table 3. Watson's software components and data contents

Software Components	Structured Text	Unstructured Text
SUSE Linux (OS)	WordNet	Encyclopedias
Apache Hadoop	DBPedia	Wikipedias
Apache UIMA	YAGO	Dictionaries & Thesauri

The software components and the data contents used inside Watson are shown in Table 3. Watson uses a complex combination of natural language processing, semantic analysis, information retrieval, automated reasoning and machine learning to answer the questions. Watson uses many existing algorithms to generate potential answers. First, the sentence is parsed. Then hypotheses are created. These hypotheses are then checked against evidence. Finally, the hypotheses have confidence levels assigned to them. If the top hypothesis has a confidence level above the threshold, Watson proposes an answer. All this is done under 3 seconds in the actual game of jeopardy.

The parallel processing inside Watson is performed by a specially designed hardware, consisting of 90 IBM Power 750 Servers with a total of 2,880 POWER7 processor cores and 16 terabytes of RAM. The software components include Apache Hadoop and UIMA (Unstructured Information Management Architecture). UIMA provides standards-based frameworks that allow analysis and annotation of large volumes of computer text. Watson used Apache UIMA for real-time content analytics and natural language processing.

AI ON THE CLOUD

Computing technology on the whole is moving on to the cloud. In the cloud computing environment, system developers and programmers as well as end-users access the systems installed in remote locations. The hardware on which the systems

are installed is networked and distributed. Current trends in AI are slowly embracing the cloud computing architecture. Watson is a case in point. After its grand success in Jeopardy!, Watson is offering its AI services over the cloud. Large scale financial and healthcare enterprises are increasingly seeking the services of AI embedded systems running in the cloud environment. The machine learning AI bots can easily operate on distributed datasets containing disparate and asynchronous data leading to useful knowledge discovery in real time necessary for business advancement. Parallel computing on millions of nodes, machine-readable information in the form of the Semantic Web and natural language query interface, all functioning in a seamless way in the cloud computing environment represent a genuine innovation that will make the future AI scalable, faster and closer to humans.

CONCLUSION

The summers and winters of AI is a metaphor for describing the ups and downs of the hype curve traced by AI in its long history. The early AI programs and Expert Systems created a sensation and consequently very high optimism. However, AI could not deliver the goods and soon entered a wintry period in its history with an all-time low funds and low activity. However, some dedicated researchers continued to work in limited areas refraining from calling their work "AI". These bore fruits with the culmination of IBM's Deep Blue defeating chess world champion in 1997, followed by IBM's Watson defeating Jeopardy world champions in 2011. True, we are far from an overall theory or framework, explaining what thinking is and how to build intelligent machines. Nevertheless, AI has made great strides and, after overcoming the *trough of disillusionment* is marching on the *plateau of productivity*. Currently, embracing the frontline cloud computing technology, AI is poised to make a further breakthrough.

KEY TERMS AND DEFINITIONS

Artificial Intelligence (AI): The science of building intelligent machines.

Cloud Computing: The distributed and parallel computing technology that allow provides users with applications and data storage over the internet. The *cloud* is a synonym for the internet.

Connectionism: Another term for neural networks.

Deep Blue: IBM supercomputer that defeated world chess champion in 1997.

Expert Systems: Computers programs styled on the knowledge and reasoning of experts.

Machine Learning: AI programs that extract useful patterns from vast amounts of data and makes unforeseen predictions based on these data, without explicit programming.

Neural Networks: Network system, modeled after the human brain, capable of learning from data.

Turing Test: A test proposed by Alan Turing in 1950 to test the intelligence of computers.

Watson: IBM supercomputer that beat human champions in the Jeopardy TV contest in 2011.

Swarm Intelligence for Multi-Objective Optimization in Engineering Design

A

Janga Reddy Manne

Indian Institute of Technology Bombay, India

INTRODUCTION

Nowadays, most of the engineering design problems are intrinsically complex and difficult to solve, because of diverse solution search space, complex functions, continuous and discrete nature of decision variables and hard constraints. Meta-heuristic algorithms are becoming popular in dealing with these kind of complexities. Evolutionary algorithms (EAs) and swarm intelligence (SI) algorithms are being population based random search techniques becoming attractive global optimization solvers. The algorithms use guided rules or heuristics inspired from nature to enable effective exploration of optimal solutions to complex engineering problems. In recent past, a number of swarm intelligence (SI) algorithms were proposed based on principles of co-operative group intelligence and collective behavior of self-organized systems. The approaches use agents to perform explorations while they interact with neighbors and the environment. However, the individual members have limited search capabilities, co-operative group intelligence and/or knowledge sharing among the swarm helps to obtain optimal solutions to complex engineering problems. The popular SI algorithms include particle swarm optimization (PSO) that was emerged from simulating the behavior of flocks of birds (Kennedy & Eberhart, 1995), ant colony optimization (ACO) that was emulating the behavior of ants foraging for food (Dorigo, 1992). Other SI algorithms include Honey-bee mating algorithm, glow swarm algorithm, bacterial Foraging and Cuckoo search algorithms etc.

Many times, practical engineering design problems are characterized by multiple conflicting goals. In contrast to single objective optimization, multi-objective optimization deals with simultaneous optimization of several non-commensurable and often competitive/conflicting objectives. Because of the multiple conflicting objectives, it may not be possible to find a single optimal solution that will satisfy all the stated goals, instead, the solution exists in the form of alternative trade-offs, also known as the non-inferior or non-dominated solutions. In the past, several studies have used classical optimization techniques such as linear programming (LP), dynamic programming (DP) and non-linear programming (NLP) to solve the multi-objective problems by adopting weighted-sum or constrained approach etc. These approaches may face difficulties while generating non-dominated solutions for practical problems. For example, in the weighted-sum approach, the multiple objectives of the problem are converted into a single objective optimization by adopting suitable weights to all the objectives. By using a single pair of fixed weights, only one point on Pareto-front can be obtained. Therefore, if one would like to obtain the complete set of Pareto optimal front, all possible Pareto solutions must first be derived. This requires the algorithms to be executed iteratively, so as to ensure that every weight combination has been evaluated. Obviously, it is unrealistic to reiterate the algorithms continually to exhaust all the weight combinations. Similarly, in the constraint method, it needs to reiterate the algorithm for a large number of times, which requires more computational effort. Also

conventional approaches may face difficulties, if optimal solution lies on non-convex or disconnected regions of the objective function space. Thus the classical approaches are not ideal to solve multi-objective optimization problems (MOOP). In developing an algorithm for solution of an MOOP, it should have an ability to learn from past performance, to direct proper selection of weights for further evolutions. To achieve these goals, multi-objective evolutionary algorithms (MOEAs) have been proposed and are suggested as effective means to deal with these issues (Reddy & Kumar, 2007a). Due to their efficiency and easiness to handle non-linear functions, ability to approximate the non-convex and disconnected Pareto optimal fronts of real-world problems, MOEAs are getting diverse applications in engineering design. Apart from that, the specific advantage of MOEAs over the classical approaches is that they generate a population of solutions in each iteration and offer a set of alternatives (Pareto optimal set) in a single run. Thus population based stochastic search techniques are becoming more popular to solve MOOPs.

In the following sections, first the principles and issues in developing multi-objective algorithms are discussed. Then swarm intelligence based algorithm for multi-objective optimization is presented. Subsequently, application of the methodology is illustrated though few multi-objective engineering design problems.

BACKGROUND

Multi-Objective Problem

A general multi-objective optimization problem can be defined as, minimize a set of functions $f(x)$, subject to p inequality and q equality constraints (Reddy & Kumar, 2007a).

$$\text{Min. } f(x) = \{f_1(x) f_2(x) \dots f_m(x)\}^T \quad (1)$$

$$x \in D$$

where $x \in R^n$, $f_i: R^n \rightarrow R$ and

$$D = \left\{ \begin{array}{ll} x \in R^n : & l_i \leq x \leq u_i, \quad \forall i = 1, \dots, n \\ & g_j(x) \geq 0, \quad \forall j = 1, \dots, p \\ & h_k(x) = 0, \quad \forall k = 1, \dots, q \end{array} \right. \quad (2)$$

where m is number of objectives; D is feasible search space; $x = \{x_1 x_2 \dots x_n\}^T$ is the set of n -dimensional decision variables (continuous, discrete or integer); R is the set of real numbers; R^n is n -dimensional hyper-plane or space; l_i and u_i are lower and upper limits of i -th decision variable.

Pareto Optimal Solution

In MOOP, the desired goals are often conflicting against each other and it is not possible to satisfy all the goals at a time, which leads to definition of *Pareto optimal* solutions. The Pareto optimal solution refers to a solution, around which there is no way of improving any objective without degrading at least one other objective.

Pareto front is a set of non-dominated solutions, being chosen as optimal, if no objective can be improved without sacrificing at least one other objective (Deb et al., 2002). On the other hand a solution x^* is referred to as dominated by another solution x , if and only if, x is equally good or better than x^* with respect to all objectives. The definition of Pareto optimality is very much useful in MOEAs to classify the population of solutions into dominated and non-dominated members, thereby helping in the selection of member solutions from one generation to next generation.

Multi-Objective Evolutionary Algorithms

In the last two decades, a number of evolutionary algorithms (EAs) were proposed to solve multi-objective optimization problems. The first generation MOEAs, Non-dominated Sorting Genetic

Algorithm (NSGA) (Srinivas & Deb, 1994) and Niched Pareto Genetic Algorithm (NPGA) (Horn et al., 1994) have received good recognition at the beginning in 1990s. Subsequently, the elitist multi-objective evolutionary algorithms were found to be more efficient than those without elitism, since the elitism helps to preserve the best solutions in the past iterations and speeds up the convergence of the solution. Of them, the second generation MOEAs, Pareto-Archived Evolution Strategy (PAES) (Knowles & Corne, 2000), Strength-Pareto Evolutionary Algorithm (SPEA) (Zitzler & Thiele, 1999) and Non-dominated Sorting Genetic Algorithm-II (NSGA-II) (Deb et al., 2002) are popular due to their efficiency in producing better Pareto front. Later on, many variants of MOEAs have been proposed over the years. Also several SI algorithms are extended to solve multi-objective optimization problems. This chapter mainly focuses particle swarm optimization based multi-objective optimization.

Studies on Multi-Objective Optimization Using PSO

The PSO algorithm has proven capabilities of quick convergence to optimal solution for single objective problems (Kumar & Reddy, 2007). The similarities of Particle Swarm Optimization (PSO) with EAs inspired the researchers to extend the algorithm to handle multiple objectives. The PSO algorithm maintains population of solutions, which allows exploration of different parts of the Pareto front simultaneously. By incorporating Pareto-dominance principle into PSO algorithm, various Multi-objective Particle Swarm Optimization (MOPSO) techniques are formulated. Ray & Liew (2002) proposed swarm metaphor approach, which uses Pareto dominance relation and combines the concepts of evolutionary techniques with the PSO. Parsopoulos & Vrahatis (2002) proposed MOPSO algorithm, adopting different types of aggregating functions to solve multi-objective optimization problems. Hu and Eberhart (2002) proposed Dynamic Neighborhood PSO, in which only one objective is optimized at

a time using a scheme similar to lexicographic ordering. A revised version of this approach, which uses a secondary population, is presented in Hu et al. (2003). Coello & Lechuga (2002) proposed MOPSO, based on the idea of having a global repository in which every particle will deposit its flight experiences after each flight cycle. Additionally, the updates to the repository are performed considering a geographically-based system, defined in terms of the objective function values of each individual. This repository is used by the particles, to identify a leader that will guide the search. The revised version of the approach is presented in Coello et al. (2004), in which a perturbation operation on decision variable space is applied to improve the performance of the algorithm. The approach of Fieldsend and Singh (2002) incorporates an unconstrained elite archive to store the nondominated individuals found during the search process. The archive interacts with the primary population in order to define local guides. This approach also uses a mutation operator that acts on the velocity value used by PSO. Li (2003) proposed non-dominated sorting PSO, which incorporates the main mechanisms of the NSGA-II into a PSO algorithm and the approach showed very competitive performance compared to NSGA-II. Reddy (2006) proposed an elitist mutated multi-objective particle swarm optimization (EM-MOPSO) for solving multi-objective problems in engineering design, and then tested its performance for solving numerical optimization problems, structural design problems, and water resources problems (Reddy & Kumar, 2007a & 2007b). In the following, the EM-MOPSO methodology for solving MOOP is explained.

MULTI-OBJECTIVE PARTICLE SWARM OPTIMIZATION

Main Issues in Developing Efficient Multi-Objective Solvers

Achieving a well-spread and global Pareto optimal front is the primary goal while solving MOOPs.

In these algorithms, apart from finding a non-dominated solution in each generation, more computational effort is necessary for preserving diversity among the generated solutions. This computational complexity is directly related to the level of diversity and distribution, which the particular algorithm aims to obtain. Therefore, the major issues in developing an effective solution approach are (Reddy & Kumar, 2007a): (i) how to guide the randomly scattered population towards the true Pareto optimal front; (ii) how to maintain good diversity in the generated non-dominated solutions. (iii) how to avoid the loss of obtained quality non-dominated solutions over the generations. These issues are also depicted in Figure 1. A good solver should address all these issues.

Elitist-Mutated Multi-Objective Particle Swarm Optimization

The EM-MOPSO procedure combines Pareto-dominance principles with PSO and uses elitism in its evolution (Reddy & Kumar, 2007a). The main algorithm consists of initialization of population,

Figure 1. Graphical illustration of main issues in the development of multi-objective evolutionary algorithm where f_1 and f_2 are two objective functions

evaluation, performing PSO operations and reiterating the search on swarm to reach true Pareto optimal solutions. In this process, the particles are first evaluated and checked for dominance relation among the swarm. Then the non-dominated solutions found are stored in an external repository (*ERP*). The size of this repository is restricted to a pre-defined number. This restriction is done, using crowding distance comparison operator (Deb et al., 2002), which gives the density measure of the existing particles in the function space. This *ERP*, with crowding operator, helps the particles to create effective selection pressure towards true Pareto optimal solutions. Also in this procedure a step wise linearly variable *ERP* is used. This helps in achieving a well distributed Pareto front and saves considerable computational time during optimization. The selection of global guides for each particle is performed by randomly choosing one solution from those stored in the *ERP*. In addition, an efficient strategic mechanism called elitist-mutation is incorporated into the algorithm. By attracting the swarm towards sparsely populated regions in *ERP*, it helps the search to uniformly distribute the non-dominated solutions along the true Pareto optimal front. Some of the main operators used in the procedure are explained below.

PSO Algorithm

In PSO each particle represents a potential solution and the position of each particle is changed according to its own experience and that of its neighbors (Eberhart & Keenedy, 1995). If the search space is D -dimensional, the i^{th} individual (*particle*), of the population (swarm), can be represented by a D -dimensional vector, $X_i = (x_{i1}, x_{i2}, \dots, x_{iD})^T$. The *velocity* (position change) of this particle, can be represented by another D -dimensional vector $V_i = (v_{i1}, v_{i2}, \dots, v_{iD})^T$. The best previously visited position of the i^{th} particle is denoted as $P_i = (p_{i1}, p_{i2}, \dots, p_{iD})^T$ and acts as a local guide to the particles. Defining g as the index of the global guide of particle, and superscripts denoting the iteration number, the

velocity and position of a particle are manipulated according to the following two equations:

$$v_{id}^{n+1} = \chi[w v_{id}^n + c_1 r_1 \frac{(p_{id}^n - x_{id}^n)}{\Delta t} + c_2 r_2 \frac{(p_{gd}^n - x_{id}^n)}{\Delta t}] \quad (3)$$

$$x_{id}^{n+1} = x_{id}^n + \Delta t v_{id}^{n+1} \quad (4)$$

where $d = 1, 2, \dots, D$; $i = 1, 2, \dots, N$; N is the size of the swarm population; χ is a constriction factor which controls and constricts the velocity's magnitude; w is the inertia weight, which is often used as a parameter to control exploration and exploitation in the search space; c_1 and c_2 are positive constant parameters called acceleration coefficients; r_1 and r_2 are functions of uniformly distributed random numbers in $[0, 1]$; Δt is the time step usually set as 1 and n is iteration number.

Elitist-Mutation

The idea underlying the elitist-mutation mechanism (Reddy & Kumar, 2007a) is to effectively explore and exploit the search space in the feasible region, where members of the repository that are isolated in the non-dominated *ERP* should be preferentially mutated and replace the worst particles in the swarm. This is performed on a predefined number of particles. At initial phase of this mechanism, it replaces the infeasible solutions with the least crowded solutions in *ERP* after performing elitist mutation on those particles, and at later phase it tries to exploit the search space around the sparsely populated particles along the Pareto fronts. This is a special mechanism which helps to overcome the drawbacks of traditional PSO algorithm, on being extended to solve MOOP. This also promotes diversity in the population and consequently helps in the search to find the true Pareto optimal front.

The elitist-mutation operator involves three key steps: (i) Randomly select one of the objec-

tives from m objectives. Sort the fitness function in descending order and get the index number for the respective particles; (ii) Use crowding distance assignment operator and calculate the density of solutions in the external repository (*ERP*) and sort them in descending order of crowding value. Randomly select one of the sparsely populated solutions from top 10% of *ERP* as guide (g). (iii) Perform elitist-mutation on predefined number of particles.

More details on elitist-mutation operator, variable size external repository, crowding distance comparison operator, and handling overlapping solutions can be found in Reddy & Kumar (2007a.)

Step-By-Step Procedure of EM-MOPSO

The EM-MOPSO algorithm can be summarized in the following steps (Reddy and Kumar, 2007a):

1. Initialize the population position and velocity vectors. The current position of the i -th particle, X_i is initialized with random real numbers within the specified decision variable range; each particle velocity vector V_i is initialized with uniformly distributed random number in $[0, 1]$.
2. Evaluate each particle in the population. The personal best position P_i is set to X_i . Identify particles that give non-dominated solutions in the current population and store them in an external repository (*ERP*). Set iteration counter, $t = 0$.
3. Select randomly a global best P_g for the i -th particle from the solutions stored in *ERP*. Calculate the new velocity V_i based on the Equation (3), and update the position X_i by Equation (4). Repeat the procedure for all the particles.
4. Evaluate each particle in the population. Then each individual is checked for dominance with its current personal best solution. Replace P_i with current solution, if the new one dominates the current P_i .

5. Set *ERP* to a temporary repository (*TempERP*) and empty *ERP*. Identify particles that give non-dominated solutions in the current iteration and add them to *TempERP*.
6. Find the non-dominated solutions in *TempERP*. If the number of non-dominated solutions is found to exceed the desired size of *ERP*, then use crowding distance operator to select the desired ones and store them in *ERP*. Empty the *TempERP*.
7. Sort the *ERP* according to crowding distance values and perform elitist-mutation operation on specified number of particles.
8. Increment the iteration counter, $t = t + 1$ and check for termination criteria. If the termination criterion is not satisfied, then go to step 3; otherwise output the non-dominated solution set from *ERP*.

To handle constrained optimization problem, the study adopted the constraint handling mechanism as given in Deb et al. (2002). This approach provides simplicity in using feasibility and non-dominance of solutions when comparing solutions. In the following sections, the application of EM-MOPSO algorithm for solving MOOP is demonstrated.

APPLICATION OF EMMOPSO TO MULTI-OBJECTIVE ENGINEERING DESIGN

This section presents the application of EM-MOPSO algorithm to structural design problems namely two bar truss design, and I-beam design. To apply EM-MOPSO and NSGA-II algorithms the same values of the parameters are used as constant parameters $c1=1.0$ and $c2=0.5$; inertial weight $w=1$; constriction coefficient $\chi=0.9$; size of external repository, $ERP=100$; the size of elitist-mutated particles is set to 20; and the maximum number of iterations used is 100.

Figure 2. The two-bar truss design problem. Minimization of cost of fabrication and minimizing stresses in members (AC and BC) are the two objectives

Two-Bar Truss Design

This problem was originally studied using the ϵ -constraint method (Palli et al., 1999). As shown in Figure 2, the truss has to carry a certain load without elastic failure. Thus, in addition to the objective of designing the truss for minimum volume (which is equivalent to designing for minimum cost of fabrication), there are additional objectives of minimizing stresses in each of the two members AC and BC.

So the design problem involves a two-objective optimization problem for three variables y (vertical distance between B and C in m), x_1 (length of AC in m) and x_2 (length of BC in m). The two-bar truss design problem in mathematical form can be expressed as:

minimize,

$$f_1(x) = x_1 \sqrt{16 + y^2} + x_2 \sqrt{1 + y^2}$$

minimize,

$$f_2(x) = \max(\sigma_{AC}, \sigma_{BC})$$

subject to

$$\max(\sigma_{AC}, \sigma_{BC}) \geq 1(10)^5$$

$$1 \leq y \leq 3 \text{ and } x \geq 0$$

The stresses are calculated as follows:

$$\sigma_{AC} = \frac{20 \sqrt{16 + y^2}}{y x_1},$$

$$\sigma_{BC} = \frac{80 \sqrt{1 + y^2}}{y x_2}$$

To apply the proposed method, the bounds on x_i are taken as $0 \leq x_i \leq 0.01$ for $i=1$ and 2. The ϵ -constraint method reported only five solutions with the following spread: (0.004445 m³, 89983 kPa) and (0.004833 m³, 83268 kPa). The Figure 3 shows the optimized fronts obtained using the ϵ -constraint method, the EM-MOPSO and the NSGA-II methods.

With EM-MOPSO the solutions are spread in the following range: (0.004026 m³, 99996 kPa) and (0.05273 m³, 8434.493 kPa) and for NSGA-II (0.00407 m³, 99755 kPa) and (0.05304 m³, 8439 kPa). Thus both have a wide variety of alternatives. But the ϵ -constraint method could not find much variety of solutions in terms of the second objective (Palli et al., 1999). If minimum volume

is desired, EM-MOPSO gives as low as 0.004026 m³ or if minimization of stress is important, it finds a solution with stress as low as 8434.493 kPa, whereas the ϵ -constraint method has found a solution with minimum stress of 83,268 kPa, which is about 10 times higher than that found with EM-MOPSO. Also the EM-MOPSO solutions are very competitive with NSGA-II solutions, both in terms of closeness to the true optimum front and in their spread.

I-Beam Design

The second design problem is taken from Yang et al. (2002). The problem is to find the dimensions of the beam presented in Figure 4. In this design problem, it should satisfy the dimensions of the geometric and strength constraints, and at the same time minimize two objectives, cross-sectional area of the beam and static deflection of the beam under the force P.

The mathematical form of the problem can be written as below

Minimize, Cross sectional area (cm²):

$$f_1 = 2 x_2 x_4 + x_3 (x_1 - 2 x_4)$$

Figure 3. Non-dominated solutions obtained using EM-MOPSO and NSGA-II for the two-bar truss design problem. The optimal solutions found by ϵ -constraint method (eps-constr) are also shown for comparison

Figure 4. The I-beam design problem. Minimization of cross-sectional area of the beam and static deflection of the beam are two objectives

Minimize, Deflection (cm):

$$f_2 = \frac{P L^3}{48 E I}$$

where

$$I = \frac{1}{12} \left\{ x_3 (x_1 - 2x_4)^3 + 2x_2 x_4 \left[4x_4^2 + 3x_1 (x_1 - 2x_4) \right] \right\}$$

subject to

$$g(x) = \sigma_a - \left(\frac{M_y}{Z_y} + \frac{M_z}{Z_z} \right) \geq 0$$

$$10 \leq x_1 \leq 80, 10 \leq x_2 \leq 50, 0.9 \leq x_3 \leq 5, 0.9 \leq x_4 \leq 5$$

$$\text{where } M_y = \frac{P}{2} \times \frac{L}{2} \quad M_z = \frac{Q}{2} \times \frac{L}{2}$$

$$Z_y = \frac{1}{6x_1} \left\{ x_3 (x_1 - x_4)^3 + 2x_2 x_4 \left[4x_4^2 + 3x_1 (x_1 - 2x_4) \right] \right\}$$

$$Z_z = \frac{1}{6x_2} \left\{ (x_1 - x_4)x_3^3 + 2x_4 x_2^3 \right\}$$

$E = 2 \times 10^4 \text{ kN/cm}^2$, $\sigma_a = 16 \text{ kN/cm}^2$, $P = 600 \text{ kN}$, $Q = 50 \text{ kN}$ and $L = 200 \text{ cm}$.

The non-dominated solutions obtained after 100 iterations using both EM-MOPSO and NSGA-II are shown in Figure 5. It can be noticed that EM-MOPSO is able to maintain uniform distribution of solutions.

The EM-MOPSO found the minimal cross sectional area as 127.9508 units for deflection of 0.05368 units and for the minimal deflection of 0.005961 units, the cross sectional area is 829.5748 units. Whereas for NSGA-II, the minimal cross sectional area is 127.2341 units with deflection of 0.0654 units and the minimal deflection is 0.0060

Figure 5. Non-dominated solutions obtained using EM-MOPSO and NSGA-II for the I-beam design problem

with cross sectional area of 829.8684 units. Thus the proposed method is able to find wider spread of Pareto optimal solutions than NSGA-II.

DISCUSSION

The swarm intelligence based multi-objective algorithms are simple to implement, yet efficient in yielding true Pareto optimal solutions. The computational complexity is also reasonable. In EMMOPSO approach, in addition to the objective function computations, the computational complexity of the algorithm is mainly dominated by the non-dominated comparison of the particles in the population, sorting and crowding distance computation. This computational requirement is comparable to that of state of the art MOEAs available at present. The results of EM-MOPSO for constrained optimization have shown that the method is yielding diverse set of Pareto optimal solutions. Thus, the use of these swarm intelligence based multi-objective algorithms having great importance for solving many practical problems in different areas of science, engineering and industrial problems.

CONCLUSION

The swarm intelligence algorithms can provide acceptable optimal solutions to many complex problems that are difficult to cope-up using the conventional methods due to their nature that may imply discontinuities of the search space, non-differentiable objective functions, non-linear relationships, imprecise arguments and function values. In this chapter, elitist-mutated multi-objective particle swarm optimization (EM-MOPSO) approach for solving multi-objective engineering design problems is presented. The EM-MOPSO method combines PSO algorithm with Pareto dominance criteria to evolve non-dominated solutions. It uses an external repository of variable size along with a crowded distance comparison operator to promote solution diversity. In addition, the methodology uses an elitist-mutation operator to keep diversity in the population and for effective exploration of Pareto optimal solutions. The results of EM-MOPSO for engineering design problems showed that the performance of EM-MOPSO approach is quite robust and providing a wide range of alternative solutions. Advantages of the proposed EM-MOPSO approach include

its adoptability and providing efficient Pareto frontiers for multi objective optimization. So it can be inferred that the MOPSO approach can be used as a viable multi objective tool for solving real world multiple objective problems. Still there is a lot of scope for research in improving the procedures, such as, automatic fine-tuning of algorithmic parameters, handling of larger number of objectives, reducing the computational complexity of the solvers, etc.

KEY TERMS AND DEFINITIONS

Crowding Distance: The crowding distance value of a solution provides an estimate of the density of solutions surrounding that solution. The crowding distance value of a particular solution is the average distance of its two neighboring solutions.

Elitist Mutation: A strategic mutation mechanism to effectively explore the solution space, thereby helps to improve the performance of the PSO algorithm.

Multi-Objective Optimization: It deals with decision making for problems that require simultaneous optimization of several non-commensurable and often competitive/conflicting objectives.

Pareto Front: Pareto front is a set of non-dominated solutions, being chosen as optimal, if no objective can be improved without sacrificing at least one other objective. On the other hand a solution x^* is referred to as dominated by another solution x if, and only if, x is equally good or better than x^* with respect to all objectives.

Pareto Optimal Solution: The Pareto optimal solution refers to a solution, around which there is no way of improving any objective without degrading at least one other objective.

PSO Algorithm: The algorithm that was inspired by co-operative intelligence of the swarm such as bird flocking, insect colonies etc.

Swarm Intelligence: It deals with algorithms inspired from co-operative group intelligence and/or collective behavior of self-organized systems, where the agents perform explorations while interacting with neighbors and the environment.

Trust and Decision Making in Turing's Imitation Game

INTRODUCTION

Trust can be defined as “confidence in relying on another person” and is the basis for “sharing new ideas with others” (Chua et al., 2012). Turing’s imitation game provides a platform for human and machine interlocutors to share knowledge and opinions through text-based communication, but more so it can “make oneself vulnerable” (ibid). This is because human participants open-up asking and answering questions, which can lead them to trust naïvely.

The susceptibility of human interrogators is one of the reasons why Turing’s imitation game is frequently dismissed as an unsuitable criterion for machine success (Hayes and Ford, 1995). It is also considered a bad idea (McDermott, 2010), and in need of updating for the 21st century (AISB, 2012). Being able to convince a human interrogator that you are human is viewed as too weak a benchmark and “highly game-able” thus a stronger test for machine intelligence is advocated (AAAI, 2015). Alternative notions to Turing’s skip around and fail to address what the imitation game, commonly known as the Turing test, actually is. Turing too, in his scholarship on intelligent machinery, bypassed definitions, so whether machines could think or not, he described ‘thinking’ as a “sort of buzzing” in his head (Turing, 1952: p. 667). Turing did warn that the concept of *intelligence* was an emotional rather than a mathematical one (Shah, 2014; Turing, 1948). The emotional context of human-machine interaction is betrayed through

trusting an unseen interlocutor in text-based conversation that they are like *oneself*, another human.

In this chapter we present a study giving the reader an opportunity to examine trust in decision-making by humans reading a transcript of a conversation between a human interrogator questioning a hidden machine and hidden human in parallel. We begin with Turing’s idea showing his imitation game is a simple and implementable scientific experiment. We contend the imitation game is a widely applicable method to compare machine performance against a human’s. In the human language imitation game, the interaction between human and machine is conducted in interview style through the prism of the latter’s capacity to answer any questions in a satisfactory and sustained manner. Additionally the test provides a means to examine the decision-making process, in natural language exchanges, and why a human bestows trust on a stranger.

BACKGROUND

Analyses and opinions on the imitation game’s salience have varied (see Shah & Warwick, 2015; Shah, 2013; Shah, 2011; Shah & Warwick, 2010). Turing evolved his ideas on an imitation game posing an interview in which a human interrogator questions a hidden entity to determine whether it is human or machine (Turing 1950; Turing 1952). This was Turing’s *viva voce* test (Shah, 2010; Turing, 1950). The ‘standard Turing test’ is accepted

as involving *a human interrogator simultaneously questioning two hidden entities at the same time* (Stanford Encyclopedia of Philosophy, 2011). Designing an experiment to implement both of Turing tests requires setting parameters interpreting Turing's description. These include:

- Adequate duration for a test;
- Number of interrogators; and
- Style of interrogation.

An evaluation is necessary of what it means *exactly* for a machine to *pass as human*: what are the implications of any pass beyond the test? Can it be used to raise awareness of human susceptibility to deception and safeguarding trust in cyberspace interactions?

In the next section the authors present Turing's scholarship on the imitation game.

Turing's Question-Answer Test

Turing derived his natural language test for a machine from a chess game that he first introduced in his 1947 lecture on 'The ACE machine' to the London Mathematical Society (Shah, 2013). In his 1948 paper 'Intelligent Machinery' Turing advanced the possibility of a machine learning from experience and competing against humans in chess. His reason for developing the imitation game, beyond chess to conversational question and answers, was the belief that language learning was one of the most accomplished of human feats (Shah, 2011). In 1948 Turing described a "little experiment" with three participants, A, B, and C, playing chess:

1. A and C are humans located in different rooms;
2. A and C are poor chess players; and
3. B is a machine operated by a mathematician.

Player C was invoked to play both A and B. Turing felt C may find it difficult to say which they are playing. In this early version of the imi-

tation game Turing did not say what C should be told about the hidden players A and B: whether C should be informed that between A, B one is the machine and the other is a human (or both A and B are machine, or both are human). Turing set the ground for a game based on hidden interlocutors answering questions from a human interrogator who cannot see or hear them (Turing, 1950). It should be noted here that Turing was not advocating a machine to simply imitate a human; he was putting forward the idea that it was possible to build machines to answer any question put to it if the machine were designed with a sufficiently sophisticated programme (Turing, 1950).

By the end of Turing's 1950 paper *Computing Machinery and Intelligence* Turing's quest to examine machine thinking could be executed in two different ways:

1. A 3-participant game in which a human interrogator questions two hidden entities *simultaneously* and determines which is human and which is machine based on their respective answers (see Figure 1), or
2. A 2-participant *viva voce* game in which a human interrogator questions one hidden entity and determines whether it is human or machine based on responses received (see Figure 2).

In 1952 Turing detailed his imitation game further elaborating his two participant *viva voce* test (Shah, 2013; Shah, 2011). Table 1 compares the *simultaneous comparison* and *viva voce* tests, both exploring a machine's intellectual capacity to engage in human-like dialogue (Shah, 2010).

The essential features in both Turing's scenarios are:

1. The questions must be put in typewritten form to ensure *fair play* to the machine so that it is not judged on "tone of voice" or "beauty" (Turing, 1950: p. 434);
2. The questions be unrestricted: the interrogator can ask any question, "introduce almost

Figure 1. Simultaneous comparison test

any one of the fields of human endeavor that we wish to include" (Turing, 1950: p. 435). Turing pointed out mathematical questions would not be effective: the human might not be able to correctly answer questions such as 'what is the square root of π ?' and

because a machine could be programmed *not* to answer math questions correctly;

3. The interrogator must be average and not be an expert about these sorts of machines (Turing, 1950: p.442) and form part of a jury panel (Turing, 1952, in Cooper & van Leeuwen, 2013: p.668).

Figure 2. Viva voce test

Table 1. Comparison of Turing's two games for his test for machine performance through Q/A

TIG Feature	1952 and 1950 Viva Voce	1950 Simultaneous-Comparison
Mode of questioning	One-to-one: human interrogator-machine or human	One-to-two: human interrogator- machine and human
Type of questions	Unrestricted	Unrestricted
Number of participants	Two	Three
Duration of Interaction	Unspecified	After five minutes
Interrogator Type	Non-machine expert	Average judge
Number of Interrogators	Panel of juries	Unspecified
Number of Tests	Judge quite a number of times	Unspecified
Language for communication (e.g. English)	Same for both interlocutors	Same for all three participants
Criteria for Test Pass: Satisfactory and sustained answers	Considerable portion of jury taken in by pretence.	"average interrogator will not have more than 70 per cent chance of making the right identification"

Duration of Turing Tests

The duration for an imitation game is debatable. It is clear that the length of any question-answer test should be realistic taking into account the state of machine dialogue technology at the time of testing. Turing stated "after five minutes" in 1950 predicting: "I believe that in fifty years' time it will be possible to programme computers, with a storage capacity of about 10^9 , to make them play the imitation game so well that an average interrogator will not have more than 70 per cent chance of making the right identification after five minutes of questioning" (p. 443). The authors take this five minutes test as the starting point to measure machine performance through question and answers. As machines improve the duration of the test can be increased until such time that machines are so intelligent that they refuse to answer questions on the grounds of outrage when its sensibilities have been crossed.

Participant Objectives

Each of the participants in a Turing test has a different purpose:

- The machine's role in the *simultaneous comparison* and in the *viva voce* is to try

and convince the human interrogator that they are conversing with another human.

- The aim of the hidden human is to act as foil for the machine and prove to the judge that *they* are human.
- The objective of the judge is to use an interrogation strategy that detects deception by a machine pretending to be human.

In the *simultaneous* version this is a difficult task for the machine, because its responses are being contrasted with a human's at the same time by the human interrogator. However the assessment of 'satisfactory and sustained' responses rests with the subjectivity of the interrogator and what they deem to be a *humanlike* response. Interrogators in practical tests have succumbed to *false-negatives* in which they have misclassified hidden human responses as *machinelike* (see Warwick, et al., 2013; Epstein, 2008).

The issue is, *what* is the kind of answer the human interrogator expects a human would give to any particular question? A reply of "don't know" (by an honest respondent) or changing the subject (as human politicians do) could be convincing, because these are dialogical features used by humans in conversation. Realising this challenge, Turing revised his predictions regarding when a machine would succeed in an imitation game

Table 2. Turing's predictions

Year	Turing's Prediction
1950	In about fifty years' time
1951a	At the end of the century
1951b	In the next millennium
1952	At least a hundred years

(Shah, 2010). Table 2 shows Turing's adjustments from 1950 "In about fifty years' time" to "at least a hundred years" in 1952.

In the next section we introduce one of the major experiments the authors have conducted implementing Turing tests.

TURING100 EXPERIMENT

Over 100 practical Turing tests were conducted on the 100th anniversary of the British mathematician's birth on June 23, 2012. The venue was Bletchley Park, UK, where Alan Turing broke naval enigma machine codes during World War Two. Turing's imitation game was executed through two scenarios side by side.

Thirty rounds were implemented over 5 sessions during the day. Each session consisted of 36 tests presenting different human participants (judges and human foils). Six tests featured in all of the 30 rounds. Six computer terminals were set up in the Interrogator-judge room. This area allowed visitors to watch proceedings and view the judges' conversations on a big screen (Figure 3). Foiling the machines, the hidden humans were seated out of sight and hearing at another series of six terminals (Figure 4).

Method and Procedure

Five award winning machines competed in the event (Shah et al., 2016). They were accommodated on unique event-only anonymous Internet websites. The machines in the tests were:

- Cleverbot,
- Elbot,
- Eugene Goostman,
- JFred/Turing Hub, and
- Ultra Hal.

Figure 3. Judge area

Figure 4. Hidden interlocutor area: hidden humans

Including the five machines 55 human participants (30 interrogators; 25 hidden humans) took part in the tests (see Warwick & Shah, 2015; Warwick & Shah, 2014a). Male and female interrogators and hidden humans were *averaged*; they scaled from experts in artificial intelligence (philosopher, computer scientists), to lay members of the public (including journalists), and students. The human participants ranged in age (from young teenagers to mature adults), and included non-first language English speakers among English-only speakers.

The experiment design embedded control tests among machine-human tests. The purpose of using control pairs was to meet Turing's recommendation: "sometimes they [interrogators] really are dealing with a [hu]man and not a machine. That will prevent them saying 'It must be a machine' every time without proper consideration" (Turing,

1952: p. 668). Human participants and spectators were unaware of these control tests. In this way the interrogators were provided with a wealth of *natural responses* among *synthetic replies* to sift through and determine human from machine.

In each round of 6 tests there were 4 *simultaneous comparison* pairs and 2 *viva voce* set-ups (Table 3).

Hence the 30 interrogators participated in one session each and judged six tests as follows:

1. Two *simultaneous comparison* Turing tests involving one human and one machine;
2. Two control *simultaneous comparison* Turing tests:
 - a. Two hidden machines, and
 - b. Two hidden humans.
3. One *viva voce* test involving a hidden machine; and

Table 3. Types of Turing tests in Turing100

Type of test	Simultaneous Comparison: Human Interrogates Two Hidden Interlocutors	Viva Voce Human Interrogates One Hidden Interlocutor
Turing test	One human and one machine	One machine
Control test	c) two machines d) two humans	b) one human

Table 4. *Eugene Goostman machine performance*

	Machine-Human Simultaneous test	Machine Viva Voce Test	Machine-Machine Control Simultaneous Test
Incorrect classifications	4	1	2 (1 outright deception; 1 'unsure' classification)

4. One control *viva voce* involving a hidden human.

Uncertainty does not inspire confidence to say one way or another. For this reason an *unsure* classification was allowed in scoring the hidden interlocutors and could be applied by judges when they really could not make up their mind whether they were talking to a human or a machine (Warwick and Shah, 2014b).

The score method allowed judges to classify the nature of the hidden interlocutors as follows:

1. In the *simultaneous comparison* tests (Figure 1):
 - a. One human and one machine, or
 - b. Both human, or
 - c. Both machine, or
 - d. Unsure for either
2. In the *viva voce* tests (Figure 2)
 - a. Human or machine, or
 - b. Unsure.

Additionally, to gauge the conversational ability of a hidden entity classified as a machine, interrogators were asked to score it from 0-100 where:

0= poor/machinelike 100=humanlike.

For a hidden interlocutor classified as *human* interrogators were asked, if possible, to identify characteristics as follows:

1. Male or female,
2. Child, teenager or adult, and
3. Native or non-native English speaker.

Results

We present a summary of the results for 144¹ successfully completed tests. These were produced from:

1. 48 machine-human *simultaneous comparison* Turing tests,
2. 24 machine *viva voce* Turing tests,
3. 24 machine-machine control *simultaneous comparison* tests,
4. 24 human-human control *simultaneous comparison* tests, and
5. 24 human control *viva voce* tests.

Jointly the five machines were incorrectly identified in 21 of the 144 tests (14.58% of the time). This is an improvement on a 2008 experiment in which the combined wrong identification rate of five machines was 8% (Shah and Warwick, 2010). However, in this experiment one machine, *Eugene Goostman* was incorrectly identified almost 30% of the time: in 24 tests *Eugene Goostman* was not correctly classified as the machine in 7 tests (Table 4).

In four of *Eugene Goostman*'s machine-human *simultaneous* tests the machine was wrongly classified as the human – instances of the *Eliza effect* (Turtle, 1997). In those same four tests the human foil was misclassified as machine (Warwick and Shah, 2015). The latter is an example of the *confederate effect* (Shah and Henry, 2005).

In the next section a transcript of a *simultaneous comparison* involving *Eugene Goostman* is presented for the reader to benchmark their own classification of 'satisfactory responses'. This conversation was used for audience participation in a public lecture² at the same venue a week after the experiment.

Table 5. Simultaneous comparison Turing test – Judge J11c in Session 5-Round 5 Terminal C

LEFT: J11c with Entity 1 H / M / Unsure	RIGHT: J11c with Entity 2 H / M / Unsure
Judge: WHAT MUSIC DO YOU LIKE? Entity1: electronica mainly and a bit of symphonic rock Judge: omg i lyke teenie tamparr Entity1: Trying to get into Grimes at the moment but struggling Judge: yeah i knooo Entity1: School of Seven Bells is the best new band I've heard recently Judge: i see dead people Entity1: Dead Cities was a good album, can't remember who by Judge: i think it was a band called the sixth sense? Entity1: Sounds about right, perhaps there's a ghost in the machine Judge: yes indeed. Entity1: Ever seen ghost in the shell? Judge: Casper the friendly ghost.	Judge: what music do you like? Entity 2: I like Eminem - because he doesn't have a thing to do with "polite-correctness". Judge: OMG i love eminem, he's my favourite artist! Entity 2: I wonder what Eminem's nick mean. I associate it only with a word "enema". But he is a cool guy, I like his "The Real Slim Shady". Judge: i know what his nick name means, his real name is Marshall Mathers. From the initials M&M phynetically sounding like Eminem. Entity 2: Eminem is a famous crapper. No, rapper... ripper... Yeah, I mean - rapper. I like his "Stan" and "The Real Slim Shady". Judge: I like "Hailies song" Entity 2: Interesting tastes. I like science fiction books, by the way. Where do you came from, by the way? Could you tell me about the place where you live? Judge: Epsom, home of the derby. yourself? Entity 2: My guinea pig says that name Derby sounds very nice. Judge: i shopuld talk with him sometime Entity 2: I think you should take some typing lessons. Or just type more accurately. Judge: that's very rude? Entity 2: Ummm... Frankly, I didn't get your question:-) Judge: "Ummm" isnt a word. i think you need typing lessons Entity 2: My thoughts are same. By the way, I still don't know your specialty - or, possibly, I've missed it?

Machine Conversation Analysis

One of the Turing test conversations from the Turing100 experiment was selected for audience analysis in another centenary event². The audience were not informed how Judge J11c classified two hidden entities in a *simultaneous comparison* test a week earlier. Each audience member was given a paper copy of the transcript and given a few minutes to read it. They were then asked to classify *Entity1* and *Entity2* as human or machine. Table 5 presents this simultaneous conversation exactly as typed by the judge and hidden entities during the test showing participants' own spelling and grammatical errors.

Misclassification of Entity1 and Entity2

A double error was made by J11c in one of the simultaneous comparison Turing100 tests. J11c misclassified both hidden entities in the machine-human test. It is worth noting here that judge J11c

was a female, a first language English speaker aged 13-15 at the time of the Bletchley Park experiment. Young adults are increasingly targets of identity fraud in cyberspace (CIFAS, 2015ab).

In Turing100 Experiment

Interrogator J11c decision

Entity1 was classified as being a machine and given a score of 20/100 for conversation ability.

Entity2 was classified as a non-native English human female.

Actual

Left: Entity1 was a human male (age range 45-64).

Right: Entity2 was *Eugene Goostman* machine developed to imitate an English-speaking child from the Ukraine.

J11c's dialogue was analysed by the audience at Turing Education Day at the same venue Bletchley Park, an event exactly one week after the practical Turing test experiment in 2012.

Audience at Turing Education Day

Audience results showed some of them made the same double error unknowingly agreeing with J11c. Seventy two members of the Turing Education Day audience completed the transcript analysis of a *Eugene Goostman* simultaneous conversation (Table 5). Of these 72 audience members:

- Almost 64% did not correctly identify either of the two hidden entities.
- 32% (23 of 72) made the same misclassification errors: Entity1 as machine and Entity2 as human.

In this independent analysis of J11c's interrogation of a male human and *Eugene Goostman* almost a third of the audience misclassified the machine as human, and the hidden human as the machine. The human interrogator from the live Turing100 experiment and the later *conversation analysts* 'trusted' the machine responses as being from a human. Can this virtual trust-giving be a risk to their interactions in e-commerce? More and multidisciplinary research is necessary to find characteristics of those most susceptible to deception in cyberspace.

Turing Tests and Trust

In the very first instantiation of Turing's imitation game implementing the *viva voce* scenario, in a 1991 'restricted' conversation test (where each interrogation of a hidden participant was restricted to one topic), a hidden human female foil was considered a machine. The 1991 winning machine, whose restricted dialogue centered on 'Whimsical Conversation', managed to convince half of the ten judges that it was human. The female answered questions restricted to Shakespeare's plays and was considered a machine by three of the ten judges. Her answers to the judges "occurred in a burst, suggesting computer output she often quoted lengthy passages verbatim. Several judges remarked that her replies seemed

too expert to be human" (Epstein, 2008: p.10). In this case, it appears three judges did not trust that human memory could hold and express knowledge deeming this trait to be machine-like.

Certainty and trust between strangers over computer-mediated communications relies on subjective confidence and assumptions. While error-making does play a role in intelligent thought, as happens in Turing test judgments (Shah et al., 2012), a higher value needs to be placed on assessing the basis of trust-giving rather than inferring it (Collins & Mansell, 2004).

Trust in Cyberspace

In cyberspace interactions trust "is the grease in the wheels of commerce" (Rappa, 2010). It is a complex notion dependent upon the "trustor's willingness to rely on an exchange partner in whom the trustor has confidence" (Delina et al., 2007: p. 12). However "electronic relationships are only effective, and electronic transactions are only conducted, if the requisite degree of trust exists among the parties" (Clarke, 2001: p. 290). It is tacit, as Bailey et al. (2009) warn, that "trust plays a critical role" for a user's believability when they are transacting on the Internet.

Clarke (2001) defines trust as "confident reliance by one party on the behaviour of other parties" (p.291). Trust in cyberspace entails a user:

1. Having confidence,
2. Relying upon,
3. Believing in, and
4. Trust is achievable.

Clarke (2001) adds "Trust differs on the relationship between the parties. Economic relationships may be direct ... however, a party may rely on another party despite having no formal relationship with them, or even much knowledge about them" (p.291). We can see examples of this in i) Turing test situations acting out 'stranger-to-stranger' interactions, ii) in cyberspace interactions receiving emails from unknowns, and iii) when

accepting web reviews of strangers as genuine following purchases on an e-commerce site. In a Turing test the interrogator does not know whom they are engaging so must rely on their subjective judgment on whether responses to their questions are from a human or a machine. We can see from the interrogation and conversational analysis presented in this chapter that people can get it wrong. In cyberspace identification errors and trust-naiveté could lead to identity theft and psychological misery as a result of financial fraud.

Again Clarke (2001) illuminates on why trust with strangers across cyberspace is different than it is in the physical world: parties have little knowledge of each other in the former, thus “cannot depend on such confidence-engendering measures as physical proximity, handshakes, body language” or “a common legal jurisdiction” (p. 292). In retail settings trust consists of credibility and benevolence (Ganesan, 1994 in Raimondo, 2000), but when parties are involved in web-based activity the ‘mutual transaction’ partners might not be of the same nature, for example when a human takes guidance from a dialogical virtual assistant such as Ikea’s Anna (Shah and Pavlika, 2005). Clark (2001) advocates corresponding virtual features to engender trust: availability of authentic information and recommendations from trusted parties, and ensuring user’s privacy online (p.292). In cyberspace the dimensions of trust include the technology, the market-place and the market participant (Mahadevan & Venkatesh, 2000, in Delina, et al., 2007: p. 13). Trust has a significant positive effect on relationship commitment and there is a significant direct effect of communication and information exchange on trust (ibid, p. 14).

FUTURE RESEARCH DIRECTIONS

Turing test experiments and post-experiment conversational analyses are an effective means to investigate and gather data on the decision-making

process and trust-giving route in human-machine interaction. Further, practical Turing tests afford an insight into behaviour in stranger-to-stranger communication that users might extend over Internet transmissions. In this sense the imitation game can be used as an exercise in educating people to mitigate risk and prevent deception in e-commerce.

Lastly, the work in this chapter is part of ongoing research. The authors are completing analysis of over 400 Turing tests, 150 of which were realised from the latest Turing test experiment conducted in June 2014. The analysis includes evaluating short questionnaires human participants completed prior to each experiment gathering data on negative e-commerce experience. The authors will report on investigation of the economics of trust in human-machine transactions in future publications.

CONCLUSION

It is a matter of time before we see a critical mass of smarter dialogue systems representing brands to characterise trust in e-commerce. It is essential we now re-evaluate how we assign trust to strangers in cyber transactions and ask for more information to learn who we are talking to. Stranger-to-stranger interactions are now the norm in our working and social lives. In this chapter the authors presented a transcript of a Turing test conversation from Turing100 experiment at Bletchley Park in 2012 in which a young adult misclassified both the human and the machine in a simultaneous comparison test. On analysis of that conversation, by an independent audience at Turing Education Day, over 30% misclassified the two hidden interlocutors in the same way incorrectly categorising the machine as human and the hidden human as machine. Before giving trust we need to seek more information and spend time checking ourselves..

KEY TERMS AND DEFINITIONS

Confederate Effect: A human is misclassified as a machine through responses to questions in computer mediated interaction.

Economics of Trust: Humans rely on their subjective values of certainty and confidence risking dependence on another party to provide goods, services or timely and relevant information in cyberspace transactions.

Eliza Effect: An artefact is attributed with intelligence. From Sherry Turkle: “our more general tendency to treat responsive computer programmes as more intelligent than they really are” evinced from “very small amounts of interactivity” tendency to “project own complexity onto the undeserving object” (1997: p. 101).

Imitation Game: A means to examine whether a machine, hidden from sight and hearing, can *think* based on its answers to any questions put by a human interrogator.

Simultaneous Comparison Turing Test: A 3-participant set-up in which a human interrogator questions two hidden entities in parallel to identify which is the human and which is the machine.

Trust: Humans believe in the honesty of other individuals.

Viva Voce Turing Test: A 2-participant set-up in which a human interrogator questions one hidden entity and decides whether it is human or machine based on received responses.

ENDNOTES

- ¹ A total of 180 tests were conducted but a technical failure in the first session caused 36 tests to be excluded from the results.

Michigan State University, USA

INTRODUCTION

Teachers and students are increasingly using mobile devices in and out of school for education and entertainment (Molnar, 2015; Nagel, 2014; Rodríguez, Strnadová, & Cumming, 2014). And along with the use of mobile technologies comes apps. Apps can support instruction for all students as well as specifically students with disabilities (Rodríguez et al., 2014; Stephenson & Limbrick, 2013). Apps can serve as assistive technology to support students with disabilities in a variety of ways, including in such areas as academics, organization, access, daily living, and communication (Bouck, 2016). The objectives of this article include:

1. Examining how apps can serve as assistive technology for students with disabilities,
2. Discussing the importance of educators not being arbitrary in their decision to select and implement apps to serve as assistive technology, such as relying on reviews, ratings, app lists, app databases, or the inclusion on a categorization on iTunes or Google Play; and
3. Presenting options for educators evaluating apps, which can assist educators in making more informed decisions for apps as assistive technology.

BACKGROUND

Mobile applications, or “apps” as they are more commonly known, are software programs specifically designed to operate on mobile devices such as tablets and smartphones; apps extend the basic capabilities of a device (Purcell, Entner, & Henderson, 2010). Apps are available pre-installed on a mobile device or are available to download through the Apple iTunes App store, Amazon Appstore, Google Play (formerly, Android Market), and Windows Store. Apps, like more traditional computer software, serve a variety of purposes for productivity (e.g., email, word processing), lifestyle (e.g., travel, fitness), gaming, entertainment (e.g., photos), social networking, education (e.g., basic math facts), and general educational topics (e.g., reference apps).

As apps and mobile devices continue to be a mainstay of daily lives, they are increasingly integrated into education. The majority of K-12 students has access to a some type of mobile device at home and/or school (Grunwald Associates LLC, 2013; Nagel, 2014). The commonly heard phrase, “there’s an app for that,” references that an app exists for any purpose imaginable in education – let alone individual’s daily lives – from learning to write the letter A to experimenting with chemical reactions. Of all of the available apps in iTunes, an estimated 80,000 are targeted specifically to K-12 education (Apple, 2015).

While the exact number of schools with specific 1:1 mobile device program or consistent access to mobile devices is unknown, it is estimated that almost half of all K-12 students have 1:1 computing or access to a device for regular use. In 2012, this number was only 23% (Molnar, 2015). While research is limited on the benefits of apps on mobile devices in education due to the newness and ever-changing nature of technology, apps can provide benefits for all students (Cayton-Hodges, Feng, & Pan, 2015; Mehdipour & Zerehkafi, 2013).

Beyond their use by teachers and for students in general, apps can serve as assistive technology. The term assistive technology refers to both assistive technology devices as well as assistive technology services; for the purposes of this article we will be considering assistive technology as assistive technology devices. An assistive device, as first defined in the Technology-Related Assistance for Individuals with Disabilities Act of 1988 (referred to as the Tech-Act; Public Law [PL] 100-40) is, "...any item, piece of equipment, or product system, whether acquired commercially, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities (29 U.S.C. Sec 2202(2))." In other words, an assistive technology device is *anything* that supports students with disability. Examples of assistive technology devices include hearing aids, braille, text-to-speech, augmentative and alternative communication devices, wheelchairs, and switches.

Given the ambiguous and seemingly all-encompassing definition of an assistive technology device, assistive technologies are often categorized by level of technology as well as purpose. While a few different purpose categorization schemes exist, a common system is the one proposed by the Wisconsin Assistive Technology Initiative (WATI), which includes 13 categories: seating, positioning, and mobility; communication; computer access; motor aspects of writing and composition of written material; reading; mathematics; organization; recreation and leisure; activities of daily

living; vision; hearing; and multiple challenges (Gierach, 2009).

In terms of level, assistive technology is frequently referred to as low-tech, mid-tech, and high-tech, although some also refer to a no-tech assistive technology (Blackhurst, 1997; Edyburn, 2005; Johnson, Beard, & Carpenter, 2007; Vanderheiden, 1984). No-tech assistive technology refers to an assistive technology that does not require a tool or device, such as a mnemonic (e.g., PEMDAS for remembering order of operations in mathematics – Please Excuse My Dear Aunt Sally for Parenthesis, Exponent, Multiplication, Division, Addition, Subtraction; Behrmann & Jerome, 2002; Blackhurst, 1997). Low-tech assistive technology devices are usually considered those that do not need a power source, such as a pencil grip or raised line paper. Low-tech assistive technologies are often associated with tools that require less training and cost less (Behrmann & Schaff, 2001; Blackhurst, 1997). Mid-tech assistive technology devices are those that typically operated via a battery power source (e.g., a calculator), cost more than low-tech devices but less than high-tech devices, and require more training. High-tech assistive technology devices are typically associated with computer or computer-like devices and are considered the most sophisticated technology options. High-tech assistive technologies usually cost the most as well as require the most training (e.g., speech-to-text) (Blackhurst, 1997; Edyburn, 2005; Johnson et al., 2007; Vanderheiden, 1984). Apps are considered high-tech assistive technologies.

APPS AS ASSISTIVE TECHNOLOGY

As alluded to in the prior section, apps can serve as assistive technology for students with disabilities. Apps fit the very definition of assistive technology – anything that can increase, maintain, or improve different capabilities (e.g., academics, communication, daily living) for indi-

viduals with a disability. While existing apps can be both be those specifically developed to be an assistive technology (e.g., the augmentative and alternative communication app Proloquo2Go), they can also be apps developed for a different function but repurposed (i.e., using the tool for a purpose other than its intended purpose) to serve as assistive technology for individuals with disabilities (Bouck, Flanagan, Miller, & Bassette, 2012; Bouck, Jasper, Bassette, Shurr, & Miller, 2013; Bouck, Shurr, Tom, Jasper, Bassette, Miller, & Flanagan, 2012; Mishra & Koehler, 2009). While apps exist to support a range of assistive technology purposes, in this article we will focus on apps to support academics (e.g., reading, writing, mathematics), organization, computer (or mobile device) access, activities of daily living, and communication.

Apps to Support Academics

Apps can support students with disabilities with regards to academics; in other words, apps can be used to support instruction in reading, mathematics, writing, and other core content areas for students with disabilities. Apps can be used in contrast to stand-alone devices or computer-based programs to provide assistance. For example, apps exist that provide text-to-speech, allowing access to electronic text to those who may struggle with reading (e.g., Natural Reader). Similarly, apps can provide access to digital books, such as Bookshare's Read2Go iOS app or Go Read Android app, which provide free accessible ebooks to qualified students with a print disability in the United States (Beneficent Technology, 2002-2015). With mathematics, apps can serve as an alternative to a separate calculator (e.g., MyScript Calculator; MyScript, 2015) as well as an alternative option to concrete manipulatives (e.g., Base Ten Blocks Math [Tapfun, Inc., 2014] or Number Line [Clarity Innovations, 2015]). MyScript Calculator, for example, provides the answer to computational problems entered via one's finger on the tablet screen.

Apps to Support Organization

Many apps exist to support organization, including reminders, alarms, and calendars and schedules. These existing apps (e.g., Reminders and Calendar app for iOS devices) can be repurposed to serve as assistive technology for students with disabilities. However, organization-based apps also specifically target students with disabilities. Examples include Choiceworks® (BeeVisual, 2015), which allows for visual schedules to be created, and the WatchMinder™ app, which provides reminders, alarms, prompts, or cues. Similarly, for students in general, apps exist to support students in terms of remembering and organizing their schoolwork and assignments (e.g., iHomework [Pilone, 2013] or inClass [inClass Inc, 2015]).

Apps to support organization can also be ones involving notetaking. In contrast to traditional paper-and-pencil notetaking, apps can provide additional aid to students with disabilities. For example, the app Notability (GingerLabs, 2015) enables students to record audio while also handwriting notes on a mobile device; Notability also allows students to share their notes with others. Another app that supports notetaking is Evernote (Evernote, 2015), which allows students to take notes on mobile devices and then sync their notes across all their computers and mobile devices.

Apps to Support Computer Access

Commonly, when one considers assistive technology to support computer access, one thinks of stand-alone devices rather than apps, such as a joystick or trackball instead of a mouse, an alternative keyboard, or switch (Bouck, 2016; Cook & Polgar, 2015). Stand-alone, dedicated alternative devices not only provide access to a computer, but also to computer-like devices, such as mobile technologies (e.g., iPad). However, apps can also provide alternative access for mobile devices. One example of app-based options to support access to a mobile technology is alternative keyboards. Rather than an actual device, an app can present

an alternative on-screen keyboard, such as ones that support the alternative keyboard arrangement of Dvorak (Cassingham, 2012). Rather than the QWERTY standard arrangement, Dvorak uses the following keys as a home row: A O E U I D H T N S and then hyphen/dash key (Cassingham). Other alternative keyboard apps exist, such as SwiftKey, Swype, and Fleksy, which all allow students to swipe letters as well as offer word prediction.

Apps to Support Daily Living

Apps for mobile technologies can also support students with daily living. For example, the built-in iOS device Photo app can be used to provide picture or video prompting to students with disabilities (Bouck, Jasper, Bassette, & Shurr, 2015; Walser, Ayres, & Foote, 2012); video prompting – or modeling – is considered an evidence-based practice for some students with disabilities (Wong et al., 2014). Other examples of ways apps can support students with disabilities with daily living skills includes apps that support everyday skills, such as lists for grocery shopping (e.g., Grocery iQ), picture and text-based recipes (e.g., How to Cook Everything), and navigating one in a community by walking or taking a bus (e.g., Google maps; Bouck, 2016).

Apps to Support Communication

Apps also support individuals with disabilities with communication. Assistive technology for communication is generally referred to as augmentative and alternative communication (AAC); AAC devices supplement or serve as an alternative medium for an individual's communication (Hanline, Nunes, & Worthy, 2007). AAC devices can be dedicated devices, which are tools specifically developed to be stand-alone AAC devices, or non-dedicated devices (Bouck, 2016). Non-dedicated AAC devices are tools repurposed to be AAC, such as an iPad that supports AAC apps.

A variety of AAC apps exist, including apps that range from free to hundreds of dollars. Another way

AAC apps differ is by their display. One display option is a grid that involves selecting symbols. A grid display is the typical display for dedicated devices; an example of a grid display AAC app is the popular Proloquo2Go (AssistiveWare, 2013). However, another display option is Visual Scene Display, which involves a photograph or image embedded with language (Ganz, 2014; Tuthill, 2014). Examples of Visual Scene Display AAC apps include Scene Speak and Scene and Heard (Sutton, 2015; Tuthill).

Challenge of Selecting Apps

Despite the prevalence of apps, including apps that can be used as assistive technology for students with disabilities, educators still face the daunting task of finding and selecting apps for implementation in their teaching and student learning. Educators use a variety of methods for finding apps to be used as assistive technology, including by searching “Top 10” app lists on Google, following education-themed hashtags such as #edtechchat or #spedchat on Twitter, searching apps mentioned at professional conferences and/or in professional development sessions, trusting the education category in iTunes, or relying on recommendations from colleagues. When finding apps these ways, educators may also find themselves relying on potentially arbitrary measures, such as ratings (e.g., 4 stars on in the App Store or Google Play), reviewer comments, or the app's inclusion on a list (e.g., “Top Ten Apps to Support Students with Disabilities”) to make decisions about their quality and educational value (Cherner, Dix, & Lee, 2014). However, alternative options exist for finding and evaluating if a particular app is an appropriate option to serve as an assistive technology.

Solutions and Recommendations

When educators are finding and selecting apps as assistive technology, a key focus should be on apps that are of high quality, developmentally

Table 1. App Evaluation Rubrics

Tool Name	App Evaluation Tool Description
App Consideration Checklist (Tammaro & Jerome, 2012)	• Five sections: (a) Sensory and Cognitive Features (auditory, visual, cognitive, sensory); (b) App Characteristics (content, design); (c) Basic Access/Input Features; (d) Advanced Accessibility Features; and e) Other • Assesses each feature using a rating scale: yes, sometimes, no, optional, N/A • Provides space for open-ended comments
App Evaluation Rubric (Weng & Taber-Doughty, 2015)	• Checklist section for basic information (purpose, function, data collection, modalities and feedback) • Uses a rating scale (disagree, neutral, agree, n/a) to evaluate features (e.g., quality of feedback and design, content, usability, individualization, support availability, and overall impression) • Authors conducted small usability study on the app evaluation tool • Open-ended sections for strengths, weaknesses and recommendations
App Evaluation Rubric for LD (Ok et al., 2015)	• Exclusively for evaluating apps for students with learning disabilities • Three primary sections: (a) Basic information (e.g., grade level, type of app; (b) Rating scale (1, 2, 3) for evaluating of each feature (e.g., examples, practice, error correction and feedback, error analysis, progress monitoring, motivation, and content error and bias); (c) Using a formula to compute a “grade” for each app based on the number of 1s, 2s, and 3s obtained • Authors conducted small usability study on the app evaluation tool

appropriate, free from violence and biases, and related to a student’s educational goals or needs (More & Travers, 2013). To aid educators in selecting apps that follow these guidelines, researchers and practitioners developed evaluation rubrics. While a range of app evaluation tools exist, the three highlighted in this article expressively focus on apps as assistive technology or apps for K-12 students with disabilities: The Apps Consideration Checklist (Tammaro & Jermonie, 2012); the App Evaluation Rubric (Weng & Taber-Doughty, 2015); and the App Evaluation Rubric for LD (Ok, Kim, Kang, & Bryant, 2015) (See Table 1 for more information on each of the tools considered).

In using the app evaluation tools, it is important for educators to ensure they use a rubric appropriate for their population and purpose. For example, the rubric by Ok et al. (2015) exclusively focuses on students with learning disabilities; this rubric would not be appropriate for apps, for example, that support communication or computer access but would be more focused on apps that address academic content areas. However, a potential benefit of the rubric by Ok et al. is the numerical rating and total score or grade obtained after completing the rubric. Although possibly limiting, the numerical rating and final grade allow for easy comparison across apps. The rubrics by Tammaro and Jerome

(2012) and Weng and Taber-Doughty (2015), in contrast, are not disability specific but can be used across disabilities as well as app purposes (e.g., communication, daily living, academics). While these rubrics are more versatile, they focus on an evaluator determining, essentially, yes/no or agree/disagree to the inclusion or exclusion of specific aspects or features within an app. Educators would still need to make a determination if sufficient key areas for their student(s) are adequately addressed prior to selecting and implementing the app.

FUTURE RESEARCH DIRECTIONS

Despite the development of education-based apps and their use in K-12 education, little research actually examines apps as assistive technology for students with disabilities. Hence, the field is ripe for research exploring if apps really do support students with disabilities as assistive technology as well as if app-based assistive technologies are as effective as stand-alone devices. While the research on mobile devices for students with disabilities increased significantly in recent years, the attention has not necessarily transferred to apps themselves. The little research examining apps as assistive technology suggest the poten-

tial for this technology, although the results do not necessarily suggest that app-based assistive technology is more effective than other options (e.g., traditional teacher instruction, paper-based options, computer-based instruction) (Bryant, Kim, et al., 2014; Bryant, Ok, et al., 2015; Weng & Bouck, in press).

CONCLUSION

Apps provide an option to serve as assistive technologies for K-12 students with a range of disabilities. Apps specifically exist or can be repurposed to support students with disabilities in a range of purposes, including but not limited to, academics, organization, computer access, daily living, and communication. Yet, it is important that educators give sufficient consideration to the educational apps implemented as assistive technology for students with disabilities. It is insufficient to rely on the placement of an app on a list or a recommendation from an organization or an individual. Rather, educators should evaluate apps as assistive technology. This article presented three rubrics for educator consideration with focus exclusively on evaluating apps as assistive technology or apps for students with disabilities. Educators need to fit the existing app rubrics to their population and purpose, as well as select one that is easy for them to use.

KEY TERMS AND DEFINITIONS

Apps: Applications or software for mobile devices.

Assistive Technology Device: Any technology that benefits or supports a student with a disability.

Augmentative and Alternative Communication Device: A piece of assistive technology specifically focused on communication; it supplements or replaces a student’s verbal communication.

Computer Access: The way in which an individual accesses or uses a computer or computer-like device.

iOS: The operating system for Apple mobile devices.

Mobile Device: Handheld computer-like devices, including tablets and smartphones.

Rubric: A method of evaluation that assesses quality.

Assistive Technology and Human Capital for Workforce Diversity

A**Ben Tran***Alliant International University, USA*

INTRODUCTION

Workforce development has evolved to describe any one of a relatively wide range of national and international policies and programs related to learning for work. This evolution, in part, is the end result of the term being frequently misunderstood: workforce development consists of job training only. Harrison and Weiss (1998, p. 5) defined workforce development as the “constellation of activities from orientation to the work world, recruiting, placement, and mentoring to follow-up counseling and crisis intervention”. However, inequality in the workplace, specifically promoting equal rights to employment for members of discriminated groups with disabilities (Kriegel, 2002; McClain, 2002) has become a widely talked about phenomenon in the business world, and is visible from an international (Jakovljevic & Buckley, 2011) paradigm. Hence, the purpose of this chapter is not on the varieties of the availability of assistive technologies (AT) and their usages based on individuals’ specified disability, so that individuals who require the usage of ATs can be of equal playing field compared to those individuals who do not require the usage of ATs. For information regarding AT and the state of AT in the past, present, and future in the United States, ADA, and the like, refer to Tran’s (2015a) article titled *Assistive Technology*. The purpose of this chapter is beyond the coverage of Tran’s (2015a) *Assistive Technology* article, such that, the purpose of this article is on the end results that AT could provide and contribute to the diverse workforce, and the role AT play in relations to workforce development—from an international perspective.

BACKGROUND

Historically speaking, from past to present, for many developing countries, legislation regarding the employment of individuals with disabilities has been criticized due to its ineffectiveness (Schall, 1998; Siegal, 2001). In particular, according to Jakovljevic and Buckley (2011), the legislation has had little or no impact on the employment status of people with disabilities (Agocs, 2002; Brett, 2000; Conlin, 2000; De Jonge, Rodger, & Fitzgibbon, 2001; De Laurentiis, 1991; Hignite, 2000; IRS, 1998; McGregor, 1991; Robitaille, 2002; Saskatchewan, 2000; Schall, 1998, Thomas, 2002). When addressing the needs of employees with disabilities, the Act and the Code both include the term *reasonable accommodation* (Tran, 2015a). Reasonable accommodation (disability accommodation) is any modification or adjustment to a job or to a working environment that will enable a person from a designated group to have access to or participate or advance in employment (Department of Labor, 2002; Tran, 2015a). It includes acquisition and modification of equipment and devices, as well as any necessary training. These devices and equipment are collectively known as assistive technologies (AT).

HUMAN CAPITAL FOR WORKSPACE DIVERSITY: ASSISTIVE TECHNOLOGIES (AT)

Human capitals [cultural and global (Tran, 2014a)] include labor market skills, leadership skills, general education background, artistic development

DOI: 10.4018/978-1-5225-2255-3.ch025

and appreciation, health, experiences, and intelligence [behavioral, emotional, cognitive, cultural (CQ), general (IQ), metacognitive, motivational, and social (Tran, 2014a)]. Human capitals are essential asset in most communities, both domestic, and international. Traditional approaches to human capital development emphasize individual responses. Quite often, individuals bear the cost, and the burden of obtaining education and training. Although many government programs have been developed to provide training, they tend to focus on specific populations and often are not well connected with local labor market conditions, as compared to nongovernmental that may have different types and levels of access and accessibility for various populations: the abled and the disabled.

Disability

There is much debate about the best way to define *disability*. The issue of definition has also been further complicated by the links to individual eligibility criteria for program and financial assistance or to legal implications. Furthermore, disability is difficult to define because it is a multi-dimensional concept with both objective and subjective characteristics. When interpreted as an illness or *impairment*, disability is seen as fixed in an individual's body or mind (Tran, 2014b; Tran, 2015b). When interpreted as a social construct disability is seen in terms of the socioeconomic, cultural and political disadvantages resulting from an individual's exclusion. Furthermore, people with disabilities, advocacy groups, legal and medical practitioners, policy-makers and the general public, all have a different view of disability. Thus, the meaning of disability has evolved and changed over the years through various perspectives, as such moral, medical, social, and human rights perspectives (Department of Education & Training, 2005).

The various perspectives have an effect not only on how we define disability, but also on social planning and program design, employment strategies, and how decisions are made regarding

such things as program eligibility (Nagi, 1965). In seeking to emphasize the distinction between impairment and disability, and promote a *social model*, the Physical Disability Council of Australia (2004) has stated:

Disability means the disadvantage or restriction caused by a contemporary social organization, which takes no account or little account of people who have impairments and the functional or behavioral consequences of those impairments, leading to social exclusion or resulting in less favorable treatment of and discrimination against people with impairments. Therefore people with disability are people with impairments who are disabled by barriers in society. [The] central theme in this definition are disabled is external to the individual and is a result of environmental and social factors (Submission by Physical Disability Council of Australia to Productivity Commission, 2004).

There are many variations of the social model, but all portray disability as a social construct created by ability-oriented and ability-dominated environments. According to the social model, even though impairment has an objective reality that is attached to the body or mind, disability has more to do with society's failure to account for the needs of people with disabilities.

Assistive Technology

The World Report on Disability [World Health Organization (WHO, 2011, p. 101)] produced by the World Health Organization and the World Bank, defined assistive technology (citing the U.S. Assistive Technology Act, 2004) as "any item, piece of equipment, or product, whether it is acquired commercially, modified, or customized, that is used to increase, maintain, or improve the functional capabilities of individuals with disabilities" (WHO, 2011). Assistive technology was defined in 1988 U.S. Technology-Related Assistance of Individuals with Disabilities Act as "any item,

piece of equipment, or product system, whether acquired commercially off the shelf, modified or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities (Brodwin, Star, & Cardoso, 2003; Tran, 2014b; Tran, 2015b). The U.K. Foundation for Assistive Technology provides a more succinct definition, namely, “any product or service designed to enable independence for disabled and older people”. This would cover not only devices and services, but also environmental adaptations such as home modifications, and would range from simple objects like walking and grab rails to complex devices like power wheelchairs (Hobbs, Close, Downing, Reynolds, & Walker, 2009).

It is widely accepted that assistive technologies are of vital importance for people with disabilities. The WHO report (2011), for example, said that they had been shown to be powerful tools to increase independence and improve participation, as long as they were appropriate for the users and for their environments. The report also noted that assistive devices had been known to be effective in reducing disability, and that they could at times substitute for support services, or at least complement them, and thus reduce the costs of care (MTAA, 2011). A content analysis of the letters to the editor in two disability-related magazines in the U.S. (Marini, Bhaktam & Graf, 2009) found that adaptive aid equipment was clearly a major concern for the people with disabilities who wrote in to these magazines. Adaptive aid and equipment was the second most frequently cited issue whereas the first most cited issue was accessibility (Thompson, Fisher, & Kayess, 2012). Despite the recognition of its importance, research on AT is still limited.

ASSISTIVE TECHNOLOGY

Interest in the potential of assistive technology to promote independence among people with disabilities arises out of concerns about quality of life, decreases in the availability of informal caregivers and a shrinking long-term care work-

force. Using AT in addition to personal services could potentially improve the quality of care, and thus improve social inclusion and defer functional declines and institutionalization (Agree, Freedman, Cornman, Wolf, & Marcotte, 2005). It is hoped that the use of AT can alleviate pressures on the existing long-term care system while at the same time improving quality of life, easing difficulties with *activities of daily living* (ADLs), and reducing the level of unmet need. Where the use of AT reduces the amount of personal care needed, public expenditures on home health care could be reduced and the responsibilities of informal care lightened.

Types of Disabilities: Impact on Employment

Not a great deal of the research undertaken has compared the types of disabilities and their impact on employment experience (Tran, 2014b; Tran, 2015b). However, research into work participation carried out by the New Zealand (NZ) Ministry of Social Development concluded that the more severe a person's disability, the lower the likelihood that the person will be in employment (Jensen, Sathiyandra, Rochford, Jones, Krishnan, & McLeod, 2004). According to this research, having a hearing impairment appeared to have a much smaller impact on employment than other disabilities, and this did not alter according to the severity of the impairment. It was noted that people who were visually impaired or legally blind were perceived by employers to be the hardest to accommodate.

Barriers to Employment

Various *barriers* to the employment and subsequent disability accommodation of people with disabilities exists, including confusion about the definitions, stereotyping and misconceptions regarding work attitudes (Global Diversity, 2000; Hignite, 2000; Schall, 1998; Services SETA, 2002; Whiting, 2001). The clause allowing escape from employing workers with disabilities due to

unjustifiable hardship, where an employer can avoid reasonable disability accommodation if it involves action that requires significant or considerable difficulty or expense (Department of Labor, 2002), is another possibility (Tran, 2015a).

Approaches to Accommodating Disability Employment

While numerous research documents have confirmed that people with a disability are valuable contributors to a diverse work force, the benefits of diversity in employment have not flowed to people with a disability. Past research such as the report prepared for the Victorian Office of Public Employment (Graffam, Smith, & Hardcastle, 2005) and Human Rights and Equal Opportunity Commission (HREOC) (HREOC, 2005) have heightened that people with a disability remain disproportionately excluded as employees. The Australian Public Service Commission, 2004) reported that in the decade between 1994 and 2004 there had been a decline in the employment of people reporting a disability as a proportion of APS employees. In 2004, people with a disability represented 3.8% of continuing Australian Public Service (APS) employees, down from 5.8% ten years prior (Australian Public Service Commission, 2004). Although such date may not necessarily be the most updated, validity nevertheless, is reliable and generalizable based on the popularity of research conducted regarding the population at hand (as compared to the abled population in the high-tech or related industries). Based on the data, the data suggests that although promoting a diverse work force is well advised, there is still much room for development and improvement in relation to people with a disability.

Accommodation for Individuals with Disability: Assistive Technologies

Assistive technologies in the workplace are necessary where the employee with disabilities is reliant on some device in order to complete assigned tasks.

Reasonable disability accommodation guidelines relate to any modification or adjustment to a job or to the working environment, which will enable a person from a designated group to have access to or participate or advance in employment (Department of Labor, 1998; Tran, 2015a). The code laid down by the Department of Labor (2002, p. 5) reflects reasonable disability accommodation guidelines as follows:

Employers should reasonably accommodate the needs of people with disabilities. The aim of the accommodation is to reduce the impact of the impairment of the person's capacity to fulfill the essential functions of a job...Employers may adopt the most cost-effective means that are consistent with effectively removing the barrier to a person being able to perform the job, and to enjoy equal access to the benefits and opportunities of employment.

A particularly appropriate example of the reasonable disability accommodation guidelines (Tran, 2015a) is “adapting existing equipment or acquiring new equipment including computer hardware and software” (Department of Labor, 2002, p. 5). Adherence to the guidelines is strongly recommended to those employers classified designated employers, who are at the same time obliged to employ people out of designed groups (Department of Labor, 1998).

FUTURE RESEARCH

Human capital for the workforce development, from an international perspective, some countries (both the developing and the developed) are more equipped to accommodate the disabled (and the abled) than other countries (both the developing and the developed). In accommodating the disabled, a great deal of literature suggested a dual approach, combining both work force diversity approaches and equal employment opportunity (EEO) approaches, to improve employment for

people with a disability. The EEO legislation is a well-recognized tool for promoting a diverse work force. Seen in its historical context, EEO promised equality of access and opportunity for under-represented groups, and, through this, social and economic change. However, while other guidelines, policies, legislations, and the like for various countries have made changes (or attempts to make changes) reflecting and addressing the changing needs of the workforce, changes have been disappointing in terms of employment of people with disabilities. Professional organizations and officers who should offer employment advice to persons with disabilities are missing in many countries, and more commonly and surprisingly, in many companies' department of human resources. Hence, a question left unanswered to date: does the value of intellectual human capitals (individuals' with disabilities) cause a change in legal accommodations or does a change in legal accommodations cause a change of value in intellectual human capitals (individuals' with disabilities)?

CONCLUSION

The international workforce must understand and utilize knowledge and competencies in order to achieve and sustain longevity. In order to address and understand knowledge and innovation as invaluable factors that affect the longevity of large organizations, to utilize and capitalize on these factors so that they can leverage the knowledge base of their organizations to build competitive advantages for their firms, one must understand what they are and their evolution (Tran, 2009). This is because human capital is an essential asset in most organizations (domestic and international), because human capital is an organization's most important asset. Hence, organizations need to be able to capitalize on human capital a source of competitive advantage. In doing so, organizations need to implement Tran's (2008) *Expatriate Selection and Retention* methodology in recruiting, as-

sessing, selecting, training, and mentoring human capitals, by focusing of individuals' knowledge, skills, abilities, and other characteristics (KSAOs). KSAOs refers to (Tran, 2008, p. 3; Tran, 2013, 2014c, 2015c):

1. Knowledge is usually defined as the degree to which a candidate is required to know certain technical material.
2. Skill indicates adequate performance on tasks requiring the use of tools, equipment, machinery, etc.
3. Abilities are physical and mental capacities to perform tasks not requiring the use of tools, equipment, or machinery.
4. Other characteristics include personality, interest, or motivational attributes that indicate a candidate will learn certain tasks, rather than whether they can do those tasks (Schneider & Schmitt, 1992: 53).

Organizations must first, focus on human capitals based on their ability, thereafter, provide modifications and accommodations, if necessary for disabled human capitals who may, upon request, require assistive technologies.

KEY TERMS AND DEFINITIONS

Assistive Technology: Any item, piece of equipment, or product, whether it is acquired commercially, modified, or customized, that is used to increase, maintain, or improve the functional capabilities of individuals with disabilities.

Behavioral Intelligence: Reflect the capability to exhibit appropriate verbal and nonverbal actions when interacting with people from different cultures.

Cognitive Intelligence: Knowledge structures and is consistent with Ackerman's intelligence-as-knowledge concept, which argues for the importance of knowledge as part of intellect.

Cultural Capital: The higher education success rates of educated parents.

Cultural Intelligence (CQ): A set of capabilities comprising mental, motivational, and behavioral components that focus specifically on resolving cross-cultural problems.

Disability: The disadvantage or restriction caused by a contemporary social organization, which takes no account or little account of people who have impairments and the functional or behavioral consequences of those impairments, leading to social exclusion or resulting in less favorable treatment of and discrimination against people with impairments.

Emotional Intelligence: Targeted at understanding one's and others' emotions, and practical intelligence targeted at solving practical problems.

General Intelligence (IQ): Person's capability for successful adaption to new cultural settings, that is, for unfamiliar settings attributable to cultural context or an individual's capability to function and manage effectively in culturally diverse settings.

Global Capital: Characterized by two major types of resources: the intangible cultural element in the form of organizational values toward globalization, and the overt cultural elements in the form of organizational routines for promoting its global values.

Human Capitals: Human capitals include labor market skills, leadership skills, general education background, artistic development and appreciation, health, experiences, and intelligence.

Metacognitive Intelligence: Control of cognition: the processes individuals are to acquire and understand knowledge.

Motivational Intelligence: Reflects the capability to direct attention and energy toward learning about and functioning in situations characterized by cultural differences.

Social Intelligence: Targeted at interpersonal relations, emotional intelligence.

Assistive Technology for Supporting Communication, Occupation, and Leisure by Children With Severe to Profound Developmental Disabilities

A**Fabrizio Stasolla***University of Bari, Italy***Viviana Perilli***Lega del Filo d'Oro – Molfetta, Italy***Adele Boccasini***Lega del Filo d'Oro – Termini Imerese, Italy*

INTRODUCTION

Assistive technology (AT) includes a wide range of electronic devices finalized at supporting children with disabilities and special needs to have an active role in the social environment and to minimize their isolation and passivity. By providing practical help to persons with disabilities, AT produce beneficial effects enhancing constructive engagement and quality of life (Borg, Larson, & Ostegren, 2011; Felce & Perry, 1995). To design an effective AT intervention program is necessary creating a solution tailored for the targeted users, and considering the targeted behaviors, tasks and environments in which programs are implemented (Reichle, 2011; Shih, 2011). The growing availability of such technologies may be considered a crucial outcome of the effectiveness of AT-based rehabilitative programs (De Pace & Stasolla, 2014).

BACKGROUND

Two categories of users have been recruited for the aforementioned programs:

1. Participants with extensive motor disabilities and normal intellectual functioning, and
2. Individuals with severe to profound developmental and multiple disabilities (i.e. a combination of intellectual, motor and sensorial disabilities).

The AT for the first category, implemented for educational and/or rehabilitative purposes, may be useful to improve literacy process (Chiapparino, Stasolla, De Pace, & Lancioni, 2011), instead the interventions for the second category may be focused on the independent access to preferred stimuli or on constructive engagement (Stasolla & Caffò, 2013; Stasolla et al., 2015).

A basic form of AT are the microswitches, that is electronic devices planned to enabling persons with disabilities to control autonomously their environment through the exhibition of small and simple behavioral responses (Holburn, Nguyen, & Vietze, 2004; Mechling, 2006; Saunders et al., 2003). For example, through a pressure microswitch, a child may receive a short listen (e.g. 10 sec) of preferred song, rather than directly switching on the computer or the CD player, not accessible to him/her, considering his/her clinical conditions (Lancioni et al., 2008), or accessible only through the help of caregivers (Lancioni, Singh, et al., 2006). Consequently, they are considered as a great educational and rehabilitative resource (Stasolla & Perilli, 2015).

Some basic guidelines are needs for the effectiveness of a microswitch-based program. First, a plausible behavioral response, naturally present in the person's repertoire and exhibited without excessive effort, should be selected. Second, a microswitch for monitoring the aforementioned response should be adapted. Third, a positive stimulation for motivating the exhibition of such response should be retained. Thus, the response cost (i.e. the effort produced to perform the behavioral response) should be highly compensated by the preferred stimuli (Lancioni et al., 2008).

A second relevant goal of AT-based program is represented by the improving of quality of life (Felce & Perry, 1995). The main construct of quality of life is happiness, which encompasses well-being, pleasure, fulfillment and satisfaction, particularly difficult to detect among people with severe to profound developmental disabilities (Lancioni, Singh, O'Reilly, Oliva, & Basili, 2005). To overcome this issue, professionals refer to behavioral signs of happiness such as smiling, laughing and energized body movements, labeling them indices of happiness (Lancioni et al., 2005) which may represent an outcome measure of positive mood (Ripat & Woodgate, 2011). Thus, interacting independently with the environment, a person with developmental disabilities should increase positive mood with beneficial consequences on the quality of life (Lancioni et al., 2008).

This chapter includes a selective overview of microswitches, describes their use and provides some representative examples concerning their applications to persons with severe to profound developmental and/or multiple disabilities. Specifically, the chapter illustrates:

1. The independent access to positive stimulation (i.e. through the use of a simple behavioral response detected by one microswitch),
2. The independent access to preferred stimuli and/or the opportunity to ask for social contact with a caregiver (i.e. through a combination of microswitch and VOCA),
3. The increase of adaptive response and reduction of challenge behavior (i.e. Microswitch-cluster), and
4. The communication, occupation and leisure skills (i.e. microswitch and computer).

For each group the chapter outlines a selection of empirical evidences, emphasizing strengths and weaknesses. Furthermore, social validation assessments, aimed at formally endorse the interventions programs by practitioners and caregivers, is pointed out. Finally, the chapter will recommend some guidelines for the future research in this topic.

METHOD

Computerized and manual searches were combined within electronic database such as SCOPUS, PSYCHINFO, PUBMED, ERIC using AT, developmental/multiple/learning/intellectual disabilities, communication impairments, quality of life, indices of happiness, positive participation and social validation as keywords. Overall, twenty-seven studies were included, considering as including criteria at least:

1. One participant between 4 and 18 years,
2. One cognitive-behavioral intervention, and
3. Empirical data.

Excluding criteria concerned:

1. Review papers,
2. Adults as participants,
3. Meta-analysis studies, and
4. Pharmacological treatments without behavioral program.

Two studies are briefly summarized within each group.

LITERATURE OVERVIEW

Independent Access to Stimulation

Six studies regarding the independent access to positive stimulation through a single microswitch and including ten participants, were selected. In two studies the microswitch was an optic sensor recording an eye blinking (Lancioni et al., 2010a, 2011). Three studies presented a pair of optic sensors monitoring lip and/or chin movements (Lancioni et al., 2005, 2006, 2009), and one study adopted tilt sensors (Lancioni et al., 2004). For example, Lancioni et al. (2004) employed a grid as a microswitch to detect hand movements of a girl with severe multiple disabilities. The grid had two mercury devices, ending with conductive leads. A lateral movement of the grid would make the mercury drop shift along the conductive leads and activate the sensor, which produced contingently brief periods of preferred stimulation. Analysis showed that the girl increased the frequency of hand movements during the intervention with respect to baseline (where stimulation was not available). The adaptive behavior was maintained during a post-intervention check, implemented one month after the end of intervention.

Stimulation Access and Asking for Social Contact

Seven studies including a total of 22 participants and a combination of one microswitch and one

or two VOCA(s) have been selected (Lancioni et al., 2008a, b, c, 2009a, b, c, 2012). The purpose of these studies was to provide participants with independent access to positive stimulation and opportunity to ask for social contact with their caregivers, and to choose between aforementioned opportunities. For instance, Lancioni, et al. (2009b) conducted two studies implementing microswitch and VOCA technologies. The first one monitored 11 participants in using a microswitch for accessing preferred environmental stimuli and a Voice Output Communication Aid (VOCA) for asking for social contact. The second study carried out a social validation assessment involving 110 students as raters. Results emphasized that all participants learned to use the microswitch and the VOCA. Moreover, the external raters favorably endorsed the use of such technology.

Increasing Adaptive Responses and Reducing Challenge Behaviors

One way to pursue the dual objective of promoting adaptive responses and reducing challenge behavior is constituted by microswitch-cluster. In a first intervention phase, the adaptive behavior is followed by contingent positive stimulation, even if at the same time a challenge behavior occurs. Then, in the cluster-intervention phase the adaptive response is positively reinforced only if the problem behavior is absent. Additionally, positive stimulation is interrupted if a challenge behavior occurred during its supply. Eight studies were retained in this section (Lancioni et al., 2007d, 2008d, 2009d, e, 2013b, Stasolla et al., 2014), including thirteen participants.

For instance, Stasolla et al. (2014) carried out a microswitch-cluster aimed at promoting object manipulation and extinguishing hand mouthing for three boys with severe autism spectrum disorders and profound intellectual disabilities. The adaptive response was detected through a wobble microswitch (that would be pulled, pushed or moved sideways), and the challenging behavior was monitored through an optic sensor

fixed on participants' chin. Data showed that all participants learned to use the cluster technology, increasing their adaptive responses and reducing their challenge behaviors. Moreover, all participants seemed to enjoy the sessions, since their indices of happiness (measured according to a 15-seconds partial interval coding system, with a 10-seconds observation interval followed by a 5-seconds recording interval in terms of presence/absence regarding the indices of happiness within the previous observation interval) improved during intervention compared to the baseline.

Enhancing Occupation, Communication and Leisure Skills

Six studies involving microswitch devices connected to computer systems for promoting engagement and communication, are included in this section (Lancioni et al., 2011b, 2012b, Stasolla, Caffò, et al., 2014; Stasolla, Caffò, Picucci, & Bosco, 2013; Stasolla & De Pace, 2014, Stasolla, Caffò, et al., 2015).

Essentially, the system automatically present different categories of events (e.g. encircled pictures matched with verbal cues), selected through a formal preference screening (Crawford & Schuster, 1993). The response (i.e. activation of microswitch), let the system open a second page, which provides different options within the previous category. A second response is required to choose the selected item. A final confirmation response may be necessary, inquiring whether participants really desired the selected item. Consequently the item would be available to participants for 8-30 seconds.

For example, Stasolla, Caffò, Picucci, & Bosco (2013) worked with three participants with cerebral palsy and severe communication impairments, presenting them a pressure sensor (circular button) connected to a computer system introducing three categories (i.e. food, beverage, leisure) including four items. Participants were required to respond (i.e. activate the pressure sensor) three times to select an item. A first activation to select

a category, a second response for an item and a third to confirm the choice. Indices of happiness were additionally monitored. Data emphasized that all participants increased their request and choices of preferred items during intervention and consolidated their performance during a post-intervention. Indices of happiness augmented as well during those phases, compared to baseline, for all the participants involved.

DISCUSSION

The positive evidences of the studies reviewed emphasize the importance of AT for children with developmental disabilities (Lancioni, Singh, O'Reilly, & Sigafos, 2011; Shih, Chang, & Shih, 2010; Sigafos et al., 2009). Outcomes are definitely higher when:

1. The response requires a low level of effort to be performed,
2. The stimulus events are powerful and motivating, and
3. The intervention time is sufficient to meet the person's learning conditions (Lancioni Sigafos, O'Reilly, & Singh, 2012; Saunders et al., 2003).

A suitable response may also include less conventional forms of behavior like vocalizations, eye blinking, or chin and lip movements (Lancioni et al., 2012; Lancioni & Singh, 2014), especially with children with very minimal motor behavior. These persons could not benefit from intervention programs involving typical motor responses and traditional microswitches (Lancioni et al., 2005; Lancioni & Singh, 2014). Providing these children with the possibility to be active and to decide about their environmental stimulation can be considered highly relevant for improving the individuals' quality of life (Lachapelle et al., 2005; Petry, Maes, & Vlaskamp, 2005). In fact, being constructively engaged and determining independently the level of stimulation, increase the person's overall satis-

faction, improve the general mood, and enhance social image and status (Browder, Wood, Test, Karvonen, & Algozzine, 2001; Karvonen, Test, Wood, Browder, & Algozzine, 2004; Petry et al., 2005; Wehmeyer & Schwartz, 1998; Zekovic & Renwick, 2003).

The selection of stimuli is provided through indirect and direct strategies, such as observations of the persons within their environment, interviews with parents, staff and caregivers, and stimulus preference screening procedures (Crawford & Schuster, 1993; Stasolla et al., 2015). Two features that could help to maximize the success are represented by:

1. The selection and use of more than one event so as to avoid saturation risks, and
2. Repetitions of the selection procedures over time to upgrade to the person's current interest (Saunders et al., 2003).

The studies summarized earlier in this chapter considered basic adaptive responses and specific forms of problem behavior or inadequate posture (e.g., hand mouthing, eye poking, and head forward tilting) (Stasolla et al., 2015). Supplementary adaptive responses and other problem behaviors may also be targeted to extend the applicability of the approach.

Despite the high potential of programs involving microswitches, one can state that they do not allow the participant to ask for social contact with the caregiver. Combining a VOCA to request caregiver attention, mediation or social contact with regular microswitches that allow direct access to environmental stimuli, may be considered a fairly straightforward strategy, as indicated by the studies reviewed earlier (Lancioni et al., 2008, 2009; Lancioni & Singh, 2014; Schlosser & Sigafoos, 2006; Sigafoos et al., 2009).

These intervention strategies seem to foster communication opportunities for those children. Participants may choose between selecting preferred item (e.g., a video or a song), asking for the mediation of caregivers or accessing the literacy

process, within the same rehabilitative program, fostering the children's communicative potential (Lancioni & Singh, 2014; Stasolla et al., 2014).

A similar consideration may be formulated for cognitive-behavioral interventions involving the use of AT for individuals with pervasive developmental disabilities and high functioning. Notably, in school settings, one may plan a computer-based intervention program aimed at providing students with learning difficulties, a wide range of academic activities, pursuing the dual objective of improving self-determination and constructive engagement on one side and eventually reducing stereotypic or challenge behaviors on the other. Eventually, one may argue that saturation is also prevented (Lancioni & Singh, 2014).

Summarizing, this chapter emphasizes that these forms of AT represent crucial educational and rehabilitative resources for children with developmental disabilities in daily contexts. However, research initiatives are necessary to extend and upgrade the aforementioned forms of technology for adapting such microswitches to different response situations and provide them with minimal invasion/contact (i.e., realizing devices that do not need to be fixed onto the person's body) (Leung & Chau, 2010).

CONCLUSION

The studies reviewed identify four intervention approaches for children with developmental disabilities with various levels of functioning. Despite the outcomes of the studies were largely positive, readers should cautiously interpret some of these findings. In fact, questions arose about:

1. Some of the measures used to determine the effects of the intervention,
2. The lack of control over the time variable, and
3. The absence of emphasis on the participants' acquisition of a constructive engagement role.

Given the aforementioned criticisms, the extension of research may be necessary. Furthermore, it is crucial to analyze the studies reviewed in terms of:

1. Size, (i.e., the quantitative relevance of the changes observed) and
2. Credibility/reliability based on the methodological conditions of the intervention programs (Barlow, Nock, & Hersen, 2009; Kennedy, 2005).

With regard to the first point, some studies reported significant changes in the participants' behavior, measured through specific scales or by means of response frequencies (Schiff et al., 2007), other:

1. Reported changes only related to behavioral ratings expressed by professionals or other representative figures involved in the intervention and/or
2. Presented partial, inconclusive or negative statistical evidence on formal measures (Barreca et al., 2003).

The outcomes of the studies using single-subject designs could be taken as more solid and reliable, because these designs allow for control over the time (history) variable (Kennedy, 2005). Quantitative relevance and credibility are the two important criteria on which judging the outcomes. A supplementary criterion could be the practical relevance of changes observed in terms of participants' environmental engagement and interaction involvement. With regard to this criterion, it might be stated that not all the studies code this outcome, but it is becoming more frequent.

FUTURE RESEARCH

In light of above, the following perspectives for future research should be investigated. First, the extension of AT for other children with developmental disabilities. Those efforts should consider:

1. The extensive literature on the use of this intervention approach in other rehabilitation trades;
2. The ethical considerations related to the participants' legal representatives right to decide on the use of such approach; and
3. The need for methodological sophistication.

Moreover, rehabilitative interventions through a microswitch-based program should consider the individual's involvement in the decision making and the positive interaction with the outside world (Lancioni & Singh, 2014).

A second extension may concern the settings, the generalization and the maintenance over time. With respect to the first point, one may design intervention programs in different settings, involving school, home, or community. With respect to the second point, one may consider different tasks, caregivers, research assistants, parents or teachers. With respect to the third point, one may systematically include maintenance, generalization and post intervention phases within those studies (Stasolla, Perilli, & Damiani, 2014).

A third extension may relate to the technologies. One may design new technological solutions responding to participants' characteristics on the one hand, and to contexts' resources on the other. With respect to participants' characteristics, one may keep in mind new technologies that ensure that participants can interact constructively with minimal effort. With respect to the second point, one should consider the financial resources available to families and to rehabilitative centers (Lancioni, Sigafoos, O'Reilly, & Sigafoos, 2012).

KEY TERMS AND DEFINITIONS

Assistive Technology: Umbrella including any technological device, equipment and/or tool ensuring people with disabilities to better function within their context and/or environment of daily life.

Constructive Engagement: Active and/or positive interaction of individuals with disabilities towards the outside world, enhancing self-determination.

Developmental Disabilities: Cognitive, intellectual, motor and/or sensorial disabilities throughout the life span.

Indices of Happiness: Signs of happiness such as smiling, laughing and/or excited body movements usually exhibited by non verbal individuals.

Microswitches: Electronic devices enabling persons with severe to profound developmental disabilities to independently and autonomously access to positive stimulation.

Quality of Life: Complex psychological construct including well-being, satisfaction, fulfillment and happiness.

Social Validation: Assessment of the effectiveness, the impact and the quality of a rehabilitative program, involving parents, teachers, students and/or caregivers external to the proposed intervention as raters.

Design, Manufacture, and Selection of Ankle–Foot–Orthoses

INTRODUCTION

Ankle-foot-orthoses (AFOs) are externally applied assistive devices that are prescribed to the patients with neuromuscular dysfunctions in order to improve abnormal lower limb motor functions. AFOs are mainly used to control the range of motion of the ankle joint, to compensate for the muscle weakness caused by different motor-neuron diseases, to improve the gait functions during post-operative stages and to optimize the efficiency of walking.

Different types of AFOs are used to treat different dysfunctions. Each type of AFOs has its characteristic function. However, AFOs with same function can have different designs that differ in material, geometry, additional mechanism and components which affect the comfort, cost of AFO and oxygen consumption of patients. Additionally, recent advances in different technology areas, such as additive manufacturing (AM), three dimensional (3D) scanning and CAD-CAM (computer aided design-computer aided manufacturing) have led to new designs and manufacturing methods for AFOs. The objective of this chapter is to provide a survey on design, manufacture and selection of AFOs.

BACKGROUND

First of all, it would be beneficial to describe orthosis and prosthesis concepts that are mostly confused with each other. Briefly, orthoses are braces to support dysfunction of a body part, while prostheses are artificial parts to replace a missing body part. Prostheses are devices for external and internal use. External prostheses, such as prosthetic legs or prosthetic breast form used after mastectomy (Lake, Ahmad, & Dobrashian, 2013), can be employed for cosmetic and also functional aims with the developments in prosthetic technology. On the other hand, internal prostheses, such as artificial knee joints (Guo, Hao, & Wan, 2016) and cataract lenses (Heys & Truscott, 2008) are devices which are surgically implanted within a body.

Orthoses are assistive devices that are used to align, protect and assist limbs or body parts besides supporting to treat deformities. Orthoses can be used for neurological conditions, injuries and congenital deformities. Orthoses are designed as standard or custom made forms from an individual mold in the shape of patient's foot. Orthoses can be divided into two classes, i.e. *i*) standard orthoses for general use and *ii*) custom made orthoses

Figure 1. Typical examples of ankle foot orthoses

that are prescribed for more complex conditions. Orthoses are used for lower extremity (Moisan & Cantin, 2016), upper extremity (Belda-Lois et al., 2006), and spine (Hofmann et al., 2016). Lower extremity orthoses have a wide range of use that are designed for hip, knee and ankle joints' immobilizations. They reduce energy consumption and pain as assisting the gait and improving the posture. Development of lower extremity orthotic technologies and new materials lead to new designs and manufacturing methods, and also affect selection criteria of orthoses.

AFOs are braces encompassing the lower leg, ankle joint and foot of the patients. AFOs provide stability in the ankle joint and biomechanical control above and below of ankle. For example, a patient with crouch gait pathology (walking with flexed knees) can reduce knee flexion during stance phase by using an AFO. Because, AFO produces a moment around the ankle joint that prevents ankle dorsiflexion in stance phase which prevents excessive knee flexion by directing the ground reaction force in front of the knee joint center. They are manufactured using metal and plastic materials. However, plastic AFOs are more preferred than metal ones, because they are lighter and more cosmetic (Franceschini et al., 2001). Also it was reported that custom plastic AFOs decrease oxygen consumption in the patients. However, the patients, who want to use AFO, should have sufficient active hip flexion to propel their legs. And their quadriceps muscle strength should be greater than four or five grade according to manual muscle test (Hsu, Michael, & Fisk, 2008).

There are several different types of AFOs for different biomechanical aims (Figure 1). Solid ankle foot orthosis (SAFO) (Ridgewell, Rodda, Graham, & Sangeux, 2015) rigidly supports ankle and prevent any movement at the ankle. Dynamic ankle foot orthosis (DAFO) provides subtalar stabilization. Unlike solid AFO models, this device allows ankle to dorsiflex and partially limits the plantarflexion (Sherief, Gazya, & El Gafaar, 2015). Hinged ankle foot orthosis (HAFO) is also a type of dynamic AFO which let the dorsiflexion exists during gait. On the other hand, HAFO is commonly used to restrict three-dimensional ankle mobility and limit the motion of ankle joint within the sagittal plane (Leardini, Aquila, Caravaggi, Ferraresi, & Giannini, 2014). Ground reaction ankle foot orthosis (GRAFO) is used to reduce excessive knee flexion (Ries & Schwartz, 2015). This type of orthoses has a solid part below the knee (pre-tibial support) which doesn't allow the knee joint moving forward. Posterior leaf spring ankle foot orthosis (PLS AFO) is used to primarily for foot drop in order to control plantarflexion during heel strike and swing phases to improve the functional quality of locomotion (Leone, 1987). All these AFOs have different characteristics, since they are designed for specific goals. Different characteristics of AFOs meet specific needs which result from injuries and diseases, such as foot drop (Everaert et al., 2013), cerebral palsy (van Beeten, Hartman, & Houdijk, 2015), spina bifida (Duffy, 1997) and hemiplegia (Nolan, Savalia, Lequerica, & Elovic, 2009).

AFO, with physical therapy combination, is widely used to provide adequate proper heel contact at initial-contact, to prevent premature heel-rise and to increase stance phase stability during walking (Rethlefsen, Kay, Dennis, Forstein, & Tolo, 1999). Solid, articulated and leaf spring AFOs are widely used in clinics which, in literature, were reported improving gait velocity and gait dynamics (White, Jenkins, Neace, Tylkowski, & Walker, 2002), preventing excessive plantar flexion in stance, providing adequate dorsiflexion in initial-contact and swing phases (Lam, Leong, Li, Hu, & Lu, 2005; Romkes, Hell, & Brunner, 2006), and improving natural position of the foot in late swing for hemiplegic children (Van Gestel, Molenaers, Huenaerts, Seyler, & Desloovere, 2008). Solid AFOs are used to prevent excessive plantar and dorsiflexion of the ankle during walking to enhance the stability in stance, reduce the abnormal motion at ankle and foot. The simplest way of creating a hinge motion in AFO is to trim material away around the ankle, which makes the material more flexible at this point. This is so called posterior leaf spring AFO, which capable of limiting plantar flexion and allowing dorsiflexion as required. The amount of dorsiflexion is directly related with the amount of trimming from the back of the ankle (Morris, 2007). On the other hand, hinged AFO is only prescribed to prevent either plantar flexion or dorsiflexion of the ankle (Morris, 2007). It was revealed in literature that dynamic parameters of walking are significantly improved by using solid and articulated AFO, although, in terms of these gait parameters, there was no significant superiority of any of these AFOs on another (Radtka, Skinner, & Johanson, 2005; Radtka, Skinner, Dixon, & Johanson, 1997; Eddison & Chockalingam, 2013).

Sophisticated analysis tools (computerized gait analysis, force platform, electromyography etc.), video based gait analysis methods (Edinburg Visual Gait Scale) or functional assessment scales (Gross Motor Functional Measure, PEDI etc.) are utilized to evaluate the gait parameters (Bella, Rodrigues, Valenciano, Silva, & Souza, 2012;

Dalvand, Dehghan, Feizi, Hosseini, & Amirsalari, 2013). These tools are valuable to compare the effects of the AFO for the patient and to tune the AFO in order to increase the influence on related gait parameters (gait velocity, step length, kinetics and kinematics).

DESIGN OF AFOS

AFO is designed to control the motion of the ankle joint, and to improve the gait function of patients with motor impairments. As shown in Figure 2a, an AFO applies forces to three different points of the limb (Edelstein & Bruckner, 2002). F_1 is applied to the proximal-posterior calf, F_2 to the foot sole and F_3 to the dorsal foot (Figure 2a). Three point pressure system will help manage the deformities such as excessive pronation and valgus angles. This system limits the motion around the joint axes and therefore rotations around the joint axes could be managed and joint stabilizations could be provided.

Stiffness, geometrical shape and material type are the main parameters which give to AFO its characteristic properties. AFO stiffness is an important parameter that directly has relation with other parameters taken into account AFO design, and should be determined properly to reduce the gait deficiencies (Esposito, Blanck, Harper, Hsu, & Wilken, 2014). AFO's stiffness depends on the type and level of deformity, and weight of patient; briefly the patients' biomechanical conditions. Different types of AFOs have different stiffness values. For example, a solid AFO should keep the ankle stable and inflexible. Therefore, they are designed thicker in the ankle section. AFO can have flexibility with a thinner thickness or a trimmed ankle section. Location of trimlines is determined according to goals such as holding ankle in fixed position, assisting dorsiflexion, allowing free dorsiflexion with free or restricted ankle plantar flexion. Also, trimline severity is an effective parameter on stiffness of AFO (Bielby et al., 2010). "How much section must be trimmed"

Figure 2. (a) Three-point force system, (b) trimlines for some design options

and “from where AFO is needed to be cut” should be determined in such a way to obtain an optimal stiffness. Therefore, geometrical shape of AFO is a key factor on determination of stiffness. Geometry and size of trimmed area and its location will affect allowed limits of the range of motion of ankle joint. Because, displacement distribution over AFO during stance phase of gait is directly related to the trimmed area in the AFO. In standard trim form, proximal trimline becomes 1.5–2 cm below the fibula head, ankle trimline must be 1 cm anterior to the tip of the malleoli and metatarsal trimline must be just posterior to metatarsal heads. For a solid AFO design, an existing standard trimline is valid (Figure 2b). If a flexible AFO is intended to be designed, then ankle trimline and anterior trimline should be moved to behind the standard ankle trimline. To control the forefoot adduction metatarsal trimline, it should be moved forward covering metatarsal heads and toes (Figure 2b).

Also trimlines affect stress distribution over the AFO, when a force is applied to it (Figure 3). It is important to distribute the stress homogeneously over the AFO to not lead to plastic deformity. At this point, it would be beneficial to take advantage of a finite element software. Finite element method (FEM) has been used for designing more efficient AFOs (Ramsey, 2011). FEM is a numerical method

to simulate the behavior of physical systems and presents time and cost effective solutions for various engineering problems. In FEM, a numerical model is constructed after the physical problem is translated into a mathematical model and then it is solved using a computer (Dhatt, Lefrançois, & Touzot, 2012). FEM enables to observe the effects of different trimlines on the stress/strain distribution over AFO models to test different AFO designs.

AFO models have free-form geometry. So it is difficult to draw a 3D AFO model with a CAD software. However, scanning technology provides having a complete 3D AFO model for analyzing in a finite element analysis (FEA) software. 3D scanning is commonly preferred for custom-made designs, prototyping, reverse engineering, industrial design, orthotic and prosthetic design, entertainment industry, inspection and digital archiving. 3D scanners basically convert the physical data of an object into digital data. The purpose of these systems is to construct a point cloud of the object. This data can be turned into 3D surface model of the scanned object and then it is possible to obtain 3D CAD model of the object. There are various systems for 3D scanning operation using different technologies such as laser, white light and x-ray scan. 3D optical scan is also one of the

Figure 3. (a) Displacement and (b) stress distribution of a trimmed AFO model

most popular scanning systems using for orthotic and prosthetic design works in biomechanics and dental areas (Balasundaram, Gurun, Neely, Ash-Rafzadeh, & Ravichandra, 2014; Kang, Kim, & Kim, 2016; Mikkelsen, Skorini, & Løgstrup Andersen, 2011). This scanning system consists of several steps (Figure 4). The object should be sprayed for obtaining matt surfaces before scanning. Different sizes of fringes are projected over the subject and then their photos are taken from different views by two high resolution digital cameras. The number of taken photos depends on size and complexity of the object. Later these photos are bought together and a point- cloud model is obtained. This model is converted into a 3D CAD model by determining surface number in the scan software. Surface number can be increased depending on the complexity of the object. At the final step, the model is verified by using deviation analysis according to a predetermined tolerance value.

Another design parameter is the material type which affects the stiffness level of the AFO. Material type is also related to other mechanical properties of AFOs. Properties, such as durability, fatigue strength, corrosion resistance and process ability depend on the material type. Moreover, material type is a determining factor in terms of the manufacturing cost of AFO. In AFO design, lightweight materials are desired and encouraged,

especially when considering young patients. Polypropylene (Bregman et al., 2010), carbon fiber (King, Mnatsakanian, & Kissel, 2015), metal (Sherk, 2008) and leather are the materials used in AFO design.

An optimum AFO design should be implemented according to the patient's specific conditions such as spastic movement, low-tone pronation, high-tone pronation or drop-foot and should provide the following properties.

An AFO should:

- Be ergonomically suitable to the patient's body,
- Minimize the skin and tissue injury as reducing or distributing the pressure around the limb,
- Prevent deformity, pain and contracture,
- Reduce consumption of energy during walking,
- Be light, durable and cosmetic,
- Be resistant against environmental effects,
- Be at reasonable cost and be produced in a proper time, and
- Be easy to use.

Hinged AFOs, which are of an important role among AFO designs, consist of a joint mechanism, and a calf and a foot component that are usually manufactured by molding technique (May & Lock-

Figure 4. Steps of 3D optical scanning

ard, 2011). The joint mechanisms that provide the control of plantarflexion or dorsiflexion are made of various materials such as metal, composite or plastic. There are also different types of joints for such functions as assisting, restricting or stopping. It is also possible to adjust the stiffness of AFO by means of some kinds of joint mechanisms (Kobayashi, Leung, Akazawa, & Hutchins, 2011). However, the stress distributes a wider area in the type of one-piece AFOs, while it is mainly concentrated around the joint in hinged type AFOs. Unless the design parameters are determined properly, then the joints, particularly metal ones, may be broken in short time. Many kinds of hinged

AFO and joints have been designed for better solutions to improve the gait function efficiently so far (Carlson, 2004; Engelman, 2010; Kobayashi et al., 2011; Kramer & Hinshon, 2016; Schwartz, 2014; Wiggin, Sawicki, & Collins, 2012), and it is still a popular research area. On the other hand, there are some studies that investigate the effectiveness of hinged AFOs for different abnormal gait conditions (Kim, Eng, & Whittaker, 2004; Rha, Kim, & Park, 2010; Tyson & Thornton, 2001). For example, it is considered that if patients have a preexisting tendency to crouch, hinged AFO may not be a good solution (Hsu et al., 2008).

MANUFACTURE OF AFO

There are many material types used for AFO manufacture such as metal, plastic, synthetic fabrics or composites. However, because it is light, cosmetic and providing support and better contact with the body, plastics are commonly prescribed. Nevertheless, they have some disadvantages such as being non-adjustable. New designs have been proposed both to provide comfort to the patient and to improve the efficiency of available designs. New designs lead to development of new manufacturing methods. The most conventional manufacturing technique is the molding process in which the lower part of the leg is casted by producing a positive cast to represent patients' shank, ankle and foot. Moreover, different manufacturing methods have been improved due to the requirements of different design and material types (Morris, 2006).

Vacuum Molding Technique

In this technique (Figure 5), a thermoplastic sheet is heated to its softening temperature in an oven. The heating time depends on the oven temperature, material thickness, material type and oven efficiency. Then the heated thermoplastic sheet is forced against the contours of a mold by an orthotist. For the purpose of better formed orthosis, vacuum pressure is also applied to the material. The molds used in this process are called positive molds. Positive molds are produced from negative molds.

Negative Mold Production

The limb is isolated with the aid of a foil. Then a rope is placed in front of the limb in order to assist to cut and remove the negative mold. The limb is wrapped with a plaster bandage applying a little impression. The ankle is held at 90 degrees of flexion in a neutral position. Once the plaster mold has been hardened, it is cut over the rope

with a cutting knife and removed from the limb. Then, the negative mold is put to the drying oven.

Positive Mold Production

The negative plaster mold is isolated and then a metal stick is placed into it. It is filled with liquid plaster and left to harden. Negative mold is removed from the positive mold. After cleaning process, positive mold is modified by scraping according to anthropometric measures of the patient, and finally mold is smoothed.

AFO Producing

A thermoplastic sheet of which thickness depends on material type, patient's weight, type and level of dysfunctions is heated in an oven. When the material has reached its softening temperature, it is wrapped around the positive mold by an orthotist. Pads and hinges should be placed to the related locations before the wrapping process. The thermoplastic sheet is pulled from their tips over the mold surface and edges of the sheet are combined by applying a moderate pressure. After the material cools, its redundant parts are cut by a scissors. Depending on prospectus there can be several design options. Once a design has been determined, trimline is marked on the orthosis and then the material is cut from the trimline. Then, locations of the straps are determined on the orthosis and they are placed. The goal of the straps is to keep the limb within orthosis in total contact. Therefore, straps should be placed at the correct angles and positions.

Carbon fiber AFOs are rather durable and light devices. They are manufactured in standard sizes for patients, but also it is possible to manufacture custom size carbon fiber AFO by using a positive mold of the patient's limb. Carbon fiber fabric layers are laid onto the modified positive mold with resin. The number and directions of layers should be arranged depending on the stiffness of the AFO.

Figure 5. Steps of vacuum molding technique: Limb is isolated with the aid of a foil and wrapped with a plaster bandage. Once the plaster mold has been hardened, it is removed from the limb and then the negative mold is obtained. The negative mold is isolated and filled with liquid plaster and left to harden. By doing so, positive mold is obtained. After cleaning process, positive mold is modified according to anthropometric measures of the patient. A thermoplastic sheet is heated in an oven. Then, it is wrapped around the positive mold. Pads and hinges are placed to the related locations before the wrapping process. The thermoplastic sheet is pulled from their tips over the mold surface and edges of the sheet are combined by applying a moderate pressure. After the material cools, its redundant parts are cut by a scissors. Trimline is marked on the orthosis and then the material is cut from the trimline. Then, the straps are placed on the orthosis

Additive Manufacturing (AM)

Additive manufacturing (AM), also known as 3D printing, is a rapid manufacturing technology that turn 3D CAD data into solid parts by using a number of additive processes, such as selective

laser sintering (SLS), direct metal laser sintering (DMLS), selective laser melting (SLM), fused deposition modeling (FDM), stereolithography (SLA) and laminated object manufacturing (LOM). Additive manufacturing is of several advantages, such as enabling freeform design,

Figure 6. Selective laser sintering (SLS)

high dimensional accuracy, reducing raw material usage, and the time to market. However, there are also several disadvantages, such as low-volume production, limited materials, high build time and surface quality depending on layer thickness (Gao et al., 2015). AM is utilized in many fields such as automotive, aerospace and biomedical industries, and can be an economical solution for customized products and creating prototype of models.

In additive manufacturing, the first step of the process is obtaining a 3D solid model. This can be accomplished by CAD software or 3D scanning systems. Then the model exported to 3D printer in stereolithography (STL) format (Ahn, Montero, Odell, Roundy, & Wright, 2002). Then the manufacturing process varying according to AM technique of the 3D printer machine is started.

SLS is one of the popular AM technique using laser (Figure 6). Parts are manufactured by sintering the powdered material. The material is heated and fused, after the laser has completed a scan process. By doing so, a layer is produced. After all layers has been produced and fused, model is completed.

There are a number of studies explore the feasibility of using SLS in AFO manufacturing. Faustini et al. (2008) evaluated the feasibility of an SLS-based manufacturing framework to produce patient-specific PD-AFOs. They reported that systematic and controlled design modifications can be possible in the AFO shape or volume which permits the exploration of the relative advantages of various passive dynamic PD-AFO designs. Another advantage is that additional design features such as holes and attachments can be easily integrated into an AFO design. Schrank (2011) reported that dimensional accuracy of the SLS process was within tolerances and material cost was acceptable. When the time saving parameter was considered, the SLS surpassed the traditional PD-AFO fabrication methods.

FDM, another popular AM process, uses production-grade thermoplastics (Figure 7). A plastic filament is wound in a coil on a spool. As material is extruded from a nozzle, the spool rotates and supplies filament to the extrusion nozzle. The material is heated in a dispenser and melted before extrusion. It hardens in a short time

Figure 7. Fused deposition modeling (FDM)

after the extrusion. The nozzle is moved along the horizontal and vertical directions by a numerically controlled mechanism (Bralla & Press, 2007; Miller, Vandome, & McBrewster, 2010). While the material is extruded as a thin ribbon on the work surface, the CAD model can be constructed layer by layer in a computer controlled pattern.

Number of AFO manufacturing researches using FDM process has been increasing day by day. In this technique, products can be manufactured within the repeatable dimensional accuracy. Patar et al. (2012) developed a DAFO prototype using FDM. The layer thickness was determined as 0.04 mm in their study. In the AFO model, ABS was used as FDM material and a DC motor provided dynamic feature of the AFO. They reported that the prototype model was much higher than the estimated cost. However, it is important to note that the cost of this model also includes a mechanism with DC motor.

Jin et al. (2015) evaluated additive manufacturing techniques of custom-made orthoses and prostheses in their review study. They concluded that AM technology enabled the fabrication of custom-made AFOs with proper fit and adequate strength, while it is not satisfied enough from the clinical, technological and economical point of views. Nevertheless, it is important to note that AM does not require molding process, which takes a considerable time, and an experienced orthoptist trimming the AFO.

There are also some researches on the process ability of materials for AM machines (Fiedler, Correa, Radusch, Wutzler, & Gerken, 2007). Additionally, some companies have been releasing new materials for AM machines. It seems that AM can be a good option for the AFO manufacturing with advancing of AM technology. The design concept for AM can be improved for more efficient products.

SELECTION OF AFOS

Developments in design and manufacture of orthoses affect the selection of the AFO. The proper selection of an AFO is crucial to support the patient during daily life activities. In this respect, biomechanical examination should be carefully implemented to ensure thorough assessment of gait functions and to gain feedback of patients' experiences properly. Generally orthoses are prescribed in order to improve patients activity of daily living (ADL) (World Health Organization, 2001). Therefore, it should be well analyzed that what the patients' gait abnormalities are, as well as the other ADL activities such as sitting, standing and even running. In order to understand the abnormalities of these different ADL activities, some functional tests or questioners should be applied to the patients or parents such as Functional Independence Measure for Children (Ziviani et

al., 2002), Gross Motor Function Measurement (Russell et al., 2000), Client Satisfaction (Bravini et al., 2014), Functional Reach Test (Bravini et al., 2014). Additionally, some sophisticated laboratories including high speed cameras, force plates and electromyography sensors are used to objectively define the movement abnormalities during standing, sitting, stair ascending-descending, reaching, walking and running. After the definition of the dynamic problem of the activity, orthotic team, which is consisted of physiotherapist, doctor and orthotic technician, get to gather in order to decide the most appropriate orthotic design for the patient. After making the decision, it should be prescribed and manufactured in a short time. During the first try, the team should be with the patients and notes the fine tunings of the AFO for the best usage in ADL. The same functional tests should be re-performed after couple of weeks in order to define the functional changes that the AFO made in patient's life.

FUTURE RESEARCH DIRECTIONS

Orthotic designs focus on the improvement of the function and stability of patients during ADL. Therefore, different movement types require different supports or facilitations. Orthoses need to be lighter, more durable, more skin friendly and smarter. If smart designs and smart materials gather with better understanding of the patients' need, the orthotics may find an important role in their life. Also it is expected that with the improvement of the additive manufacturing techniques, more subject-specific AFOs would be fabricated, thereby leading to eliminate the most of the problems stemmed from the standard and common approaches on patients with different demands and diseases.

CONCLUSION

This chapter is intended to be useful for the orthotists, physiotherapists and engineers as well as the other health specialists who are eager to know about the usage of AFOs, their different designs, and different ways of their manufacture. Finally, we emphasized the importance of the evaluation of the patients and clearly understanding of their functional difficulties by using some well-known tests and questionnaires.

KEY TERMS AND DEFINITIONS

AFO: Ankle-foot-orthosis is an assistive device designed to improve abnormal lower limb motor functions.

AM: Additive manufacturing is the rapid manufacturing technology that converts 3D CAD data to physical model by such methods as selective laser sintering, direct metal laser sintering, selective laser melting, fused deposition modeling, stereolithography, laminated object manufacturing and etc.

Gait: A manner of walking that shows the sequence of foot movements and also other parts of the body.

Orthosis: Externally applied bio-mechanical device to the body parts to control their motions and also provides protection and support.

Stiffness: An important AFO design parameter that is the resistance of the AFO to deformation by an applied force.

Trimline: Border of the trimmed section of the orthosis that is an important parameter in determining of AFO stiffness.

Vacuum Molding: A common AFO manufacturing technique in that heated sheet of plastic is laid over a positive lower limb mold and formed by the help of vacuum.

A Disability–Aware Mentality to Information Systems Design and Development

Julius T. Nganji

University of Ottawa, Canada

INTRODUCTION

Nowadays, it is difficult to imagine a world without technology. We interact with technology every day in various ways. This inevitable modern technological revolution has meant that many services are increasingly being offered online. Amongst these services e-learning, e-commerce and e-health are most common. With the drive to use technology for delivering services online, a lot of the technological developments around these areas by default have often focused on meeting the needs of people without disabilities, thus leaving people with disabilities to seek appropriate assistive technologies in order to interact with such systems. In some cases, such assistive technologies might not be compatible with these systems. There are legislations in various countries around the world necessitating that people with disabilities be included in services that are offered, by ensuring that these services are accessible to them; otherwise “reasonable adjustments” or “reasonable accommodation” need to be made in order to meet their needs.

A lot of the difficulties people with disabilities face when interacting with most information systems are related to the lack of consideration of the needs of people with disabilities during the development cycle. In designing technological solutions, designers and developers need to understand that disability could affect different functions related to the senses and how this happens. Such designers need to develop a new mind set when it comes to designing systems that will be used by everyone. The difficulties and failures of

existing information systems towards people with disabilities have necessitated the search for a better approach for designing and developing information systems. Thus, this article aims to propose a disability-aware approach to information systems design and development in order to ensure that adequate analysis of the needs of potential users with disabilities is carried out and that their needs are incorporated into the design. It also ensures that a representative group of people are selected and involved in the design process. That way, useful feedback is obtained and cost of production is reduced as designers do not have to spend a lot of money retrofitting accessibility. By developing a disability-aware mentality to systems design, the result is an accessible and usable product.

In the following sections, the difficulties that people with disabilities face when using technology will be discussed through a review of literature. The disability-aware approach to information systems design will then be proposed. The recommendations from students with disabilities on how to design e-learning to meet their needs will then be presented after which future research will be discussed, before a conclusion of this article.

BACKGROUND

In order to set the scene for proposing a disability-aware mentality to information systems design and development, this section reviews literature relating to the difficulties that people with disabilities face while interacting with information systems, some assistive technologies for interacting with

DOI: 10.4018/978-1-5225-2255-3.ch028

information systems and also reviews some approaches used in designing information systems.

Difficulties Encountered by People With Disabilities When Using Information Systems

It is a fact that people with disabilities are generally more disadvantaged than those without disabilities when accessing services for various reasons which could include the way the environment has been designed to accommodate their needs or how society responds to their needs in various ways. Environmental factors such as the weather, specifically during winter where there have been heavy snowfalls for instance have been barriers to people with wheelchairs accessing community services (Ripat, Brown, & Ethans, 2015). The way society is designed tends to favor people without disabilities. Thus, it is common even nowadays to see newer buildings being designed without accessibility in mind (e.g. no ramps or elevators for wheelchair access). Nevertheless, there is an increase in awareness of the needs of people with disabilities when constructing buildings, perhaps because it is mandated by disability legislations. Also, many older buildings are being adapted to meet the needs of people with disabilities, such as adding ramps for wheelchair access, including induction loops in meeting halls, controlling the lighting of buildings to suit people with light sensitivity and many other adaptations. Steyaert (2005) observed that such accessibility principles are not necessarily being translated from the physical environment into the electronic environment, leading to numerous difficulties for learners with disabilities, when considering an educational environment.

The severity of disabilities such as visual impairment may range from low vision to complete blindness. In the latter case, medical interventions such as eyeglasses, contact lenses or even surgery might not result in a permanent solution. People with this severity level will have to employ assistive technologies such as screen readers in order to

read information that is found in electronic format or through the use of digital Braille amongst other interaction methods. In education, students with visual impairments are often more disadvantaged than students with other disabilities when using technology (Kelly & Smith, 2008). There is no wonder therefore why a lot of the guidelines for designing inclusive solutions tend to use this group of people as example when discussing accessibility. For people with visual impairments to use web-based information systems many accessibility considerations, including the need to include alternative texts in images (Nganji, Brayshaw, & Tompsett, 2013) need to be adhered to. As visual impairment affects the sense of sight, if information systems are not designed accessibly with the needs of such users in mind, the result will be significant difficulties trying to interact with such systems which in extreme cases could also lead to incompatibility with assistive technologies such as screen readers. For people with low vision who do not necessarily have to rely on screen readers to read text on an information system, there is great need to ensure that they can be able to manipulate the text through increasing its size for more visibility in addition to providing responsive design.

Dyslexia is the most common disability affecting learning, particularly reading. It affects word recognition and spelling in an individual. There are a number of assistive technologies that could help students with dyslexia. Tools such as Read&Write help with writing and spelling. The amount of information that is presented in an information system as well as how the information is presented could determine if an individual with dyslexia would understand the information. Smaller chunks of information that is clearly written could be helpful.

Individuals with hearing impairment may have partial or complete loss of hearing. Depending on the severity of the impairment, individuals may rely on hearing aid or sign language in order to understand information that is being conveyed. Thus, it is important for designers and developers

of information systems to take these into consideration during design.

Amongst people who will also need to access information systems are people with upper limb mobility difficulties. For these people, using the mouse or keyboard may be difficult. Thus, their needs should be taken into consideration during design.

Assistive Technologies for Interacting With Information Systems

To help overcome the difficulties encountered by people with disabilities when using information systems that are not disability-aware, a wide range of assistive technologies have been implemented. When compatible with information systems, these technologies can greatly facilitate access to information to those who would otherwise not be able to access such information due to disability. A few of such technologies will be discussed here.

For people with visual impairments ranging from low vision to complete blindness, screen magnifiers and screen readers are the main technologies. Some of the most common screen readers available are JAWS (Job Access with Speech) and NVDA (NonVisual Desktop Access) and have been used in research studying adoption of screen readers (McCarthy, Pal, & Cutrell, 2013). MAC operating systems have a screen reader known as VoiceOver which can be used to read out text. Screen readers generally work by converting text into audio format so that the visually impaired person can then listen to the information they could not otherwise read. A lot of mobile devices nowadays have screen reading software that enable people to interact with information, also incorporating speech-to-text software. Thus, users can search the web through voice input and obtain results, could dial someone through speech commands amidst many other functions.

There are also some assistive technologies for people with hearing difficulties, which work to improve hearing. These are generally known as assistive listening devices (ALDs). These do not

work for people who are completely deaf as they cannot hear any sound. According to Kim and Kim (2014), ALDs “usually use microphones to capture an audio source and broadcast it wirelessly over a frequency modulation (FM), infra-red, induction loop, or other transmission techniques.” For people with hearing impairment, videos need to contain captions in order to be accessible to them. When captions are included, users can understand the content of the video. Some readers may be confused over the difference between subtitles and captions. Subtitles are often used to translate the speech in a video into a different language (e.g. the video is in English but subtitles could be in French so that French viewers would understand the video) while captions are subtitles that help people with hearing impairment to understand the video. The captions could be turned on or off but not subtitles. To make videos accessible, transcripts of the video could also be included when there are no captions. The transcript is a text version of the words spoken in the video. Research has shown that users would interact more with subtitles than with transcripts (Grgurovic & Hegelheimer, 2007). Also available to people with hearing impairment are text telephones which enable communication by typing and then displaying the typed information for the individual on the other end to read.

For people with dyslexia, various assistive technologies such as word processors and spell checkers help with writing, voice recognition software (e.g. Dragon NaturallySpeaking, Kurzweil) convert speech to text and could be very useful. In a literature review on the use of assistive technologies by students in higher education, Pino and Mortari (2014) found that the spellchecker is useful in finding spelling mistakes but it also displays a list of possible words which, for a student with dyslexia could be difficult to decipher which one is the correct word. They also reported that voice recognition software was very useful to students. However, students did not find tape recording very useful to them due to the amount of time they will spend in listening to the tape.

Approaches and Methodologies for Designing Information Systems

There are several approaches to information systems design. This section will focus on traditional methods, often used in software engineering by discussing the waterfall and the spiral methods and will also look at approaches that are common to designing user interfaces such as user-centered design, participatory design and inclusive design.

The waterfall method (Royce, 1987) was inspired by engineering disciplines such as civil and mechanical engineering and is sequential; progressing through the phases of conception, initiation, analysis, design, construction, testing, implementation and maintenance. This method is weak in that the development progresses downwards and each phase must be completed and signed off for the next phase to begin. Thus, designers would have to go back to the phase where a problem has been identified and start again from there. In reality, information systems development does not proceed as such. Also, when following this methodology, designers do not emphasize on the needs of people with disabilities during the analysis phase, thus the resultant product is not accessible to them.

The spiral method (Boehm, 1988) is intended for large, expensive and complicated projects. It has four phases that are adopted from other methods such as the waterfall method or incremental method, which include: planning (determining objectives), risk analysis (identify and resolve risks), engineering (development and testing) and evaluation (planning the next iteration). This method involves high costs and is suitable for large projects. However, this is not suitable for smaller information systems design projects.

User-centered design (Helander, Landauer, & Prabhu, 1997; Nielsen, 1993; Norman, 1988) focuses on designing information systems that would meet the needs of the user. The user is supposed to be the main focus of the design. However, when this method has been used, the focus has often been on users without disabilities. Thus, the

resultant product is not accessible to people with disabilities. Participatory design (Kyng, 1991; Muller, 1996) on the other hand seeks to involve all stakeholders, including the intended users in order to design an information system that is usable to them.

Despite the intention of participatory and user-centered design to develop products that meet the needs of users, Gregor et al. (2005) asserted that these approaches often do not address how to meet the needs of people with disabilities and those of older users. Thus, inclusive design seeks to focus on the needs of people with disabilities. Newell et al. (2010) also asserted that such approaches do not meet the needs of people with disabilities as most of the products might not be usable to older people and people with disabilities.

A DISABILITY-AWARE APPROACH TO INFORMATION SYSTEMS DESIGN AND DEVELOPMENT

Before discussing the disability-aware approach to information systems design and development, it is fitting to first discuss some reasons for developing inclusive systems. There are numerous reasons but three will be discussed here. Firstly, the number of people with disabilities is on the rise. The World Health Organization (WHO) estimates that there are over a billion people with disabilities, constituting about 15% of world population (WHO, 2015). It is morally correct to include everyone in society and designing accessible and usable systems is one way to ensure the participation and contribution of everyone, regardless of their ability or disability. Secondly, the increasing number of people with disabilities also shows that they can contribute to the economy. Bowtell (2015) reports that research has dispelled the myth that people with disabilities are poor; and has on the contrary shown that people with disabilities have a sizable spending power on accessible services. For designers to be part of this, they need to design accessible and usable systems. Thirdly, it

A

is a legal requirement in most countries to offer accessible services, which include designing accessible information systems. Those who don't comply with legislation such as the Accessibility for Ontarians with Disabilities Act (AODA), the Equality Act 2010 in the United Kingdom and the Americans with Disabilities Act (ADA), just to name these, could be prosecuted.

As already discussed, the focus of most designers and developers of information systems is on meeting the needs of users without disabilities, thus the resultant products are not accessible or usable for people with disabilities. A more inclusive approach to designing information systems is the paradigm of user-sensitive inclusive design (Newell & Gregor, 2000). The authors assert that “inclusivity” is more achievable than “universal design” and “design for all”. Additionally, in this approach, designers develop an “empathetic” relationship with the end users.

The disability-aware approach in this article is a form of user-sensitive inclusive design approach that focuses on the needs of people with disabilities. It advocates that designers and developers should always think about the needs of the users, particularly those with disabilities when designing systems. A common issue with most systems is that even when they are designed to meet the needs of people with disabilities, they often neglect the needs of people with multiple disabilities (Nganji & Brayshaw, 2015). Designing accessible systems does not only benefit people with disabilities, but will be usable to people without disabilities since needs analysis includes everyone's needs.

A disability-aware approach can be applied to the design of all systems that are required to be used by humans, including in fields such as software engineering (Nganji & Nggada, 2011). The key components of the approach as depicted in Figure 1 include:

People With Disabilities

People with disabilities are the focus of this model since information systems need to be designed to

meet their needs. They need to participate in the needs analysis phase of the development cycle in order to ensure that the product meets their needs. Given that disability is an individual experience, their input will be very useful. They will need to participate by giving feedback to the designers or developers of information systems through expressing how the system could meet their needs as well as during the testing phase. However, they could be available at any time during development cycle to be consulted.

Assistive Needs of People With Disabilities

In designing an information system, the assistive needs of people with disabilities need to be taken into consideration. When this is done at the beginning of the development cycle, designers and developers of such systems could incorporate these needs into the design. When this is done correctly, it could eliminate the need for the user to acquire a standalone assistive technology to use with the system. This also helps to solve incompatibility issues that may arise with using some assistive technologies. In determining the assistive needs of the users, designers need to involve the users themselves but could in addition, consult experts in the domain as well as obtain input from existing literature. Thus, a complete analysis of such needs is necessary to ensure that the product is both accessible and usable.

Designers and Developers of Information Systems

The designers and developers drive the development of information systems. They are very important in the process and need to develop the mentality of working with users and constantly thinking about how to meet their needs. Also, developing an empathetic relationship with users as recommended by Newell and Gregor (2000) will ensure that the system is accessible and usable.

Figure 1. Disability-aware approach to information systems design and development

Information Systems Funding Bodies

Critical to the success of the information system project is the source of funding. Enough funds would be needed in order to involve end users in the project and to carry out usability and accessibility testing of the system. Thus, funding bodies could contribute financially to ensure that good quality systems which are bug-free are released.

IMPLEMENTING A DISABILITY-AWARE APPROACH: RECOMMENDATIONS FROM STUDENTS WITH DISABILITIES

In application to the field of education, 30 students with disabilities at a United Kingdom university

and 18 students with disabilities at a Canadian university were consulted on their opinions to designing e-learning systems to meet their needs. This was done during the evaluation of a piece of software and they had some useful recommendations, which could also be applied to the design of other information systems. During the evaluation, the author also observed their interactions and preferences which are also included in the following recommendations, some of which are presented in Figure 2.

Grant Users Control Over Font Sizes and Background Color

Some students with disabilities, particularly those who had low vision and those with dyslexia found it frustrating when they could not manipulate the

size of fonts that were used in designing e-learning systems. Students with low vision have limited vision, so, in the absence of a screen magnifier to increase the font size, they would need the ability to increase the font size in order to read the information that is presented. This needs to be done without distorting the presentation. Thus, designers need to consider this. Such considerations should also be made when designing for mobile devices.

Students with dyslexia found the ability to change the type of font as well as its size in combination to the background color very useful. Thus, designers should consider granting users choice over the background color. This color contrast, although it may not be very useful to some people, are very important to others. On meeting their needs in an e-learning system, a student with both dyslexia and hearing impairment had this

recommendation: “the way that learning environments could adapt to my learning disabilities and hearing difficulties would be if I can change the text and the background color so that the text is much clearer for me to read.”

Embed Assistive Technology in Information Systems

During the needs analysis phase of the system design, a complete analysis of the needs of the user is necessary, including assistive needs. Once this is done, there is need to directly include functionalities that act as assistive technologies in the design. For instance, for a user with low vision, it would be useful to include the ability to magnify various sections to facilitate reading. The ability to check spelling, including help with writing could be very useful for some people with dyslexia.

Figure 2. Some design considerations for some disabilities

Present Information in Multiple Formats

People have preference for different formats of information. In the case of students with disabilities for instance, learning materials could be presented in various formats, including digital Braille, text (e.g. PDF, Word, HTML), audio and video with captions. For learners who are blind, the Braille format will be very useful, as will the audio and text formats. The text formats in this case could be read out loud by an inbuilt screen reader. For an individual with hearing impairment, both audio and video need to be captioned. On designing learning environments to meet their needs, a student with hearing impairment had this to say: “Even if there is no video available, it is nice to pair audio and video formats- it helps to keep track of reading and set a pace”.

Consider Implementing Multimodal Interaction

Interacting with information systems and inputting information is not just limited to using a physical or virtual keyboard. In order to fully meet the needs of all users with disabilities when interacting with information systems, designers need to consider implementing multimodal interaction interfaces. People have different ways of interacting with systems and this may be due to disability. An individual with an upper limb mobility difficulty who cannot use their hands could benefit from using a speech-to-text software. Those who are paralysed but could still see and can move their head around could benefit from eye tracking interactions.

FUTURE RESEARCH

Designers and developers of information systems are becoming more aware of the needs of people with disabilities, due to the existence of several legislations and also due to many sensitizations and the existence of standards such as the Web

Content Accessibility Guidelines (WCAG 2.0). Although it is not yet the case, in future each designer will by default look to the needs of people with disabilities in order to design an information system, without which their product will not be adopted by many organizations. By default, people will design for accessibility and usability. Future research should look at the possibility of incorporating multimodal interactions in information systems and also automatically adapting to the needs of the user.

Given that some assistive technologies are incompatible with some information systems, it is worth researching how compatibility issues could be resolved for various assistive technologies.

CONCLUSION

Most information systems are not designed with the interest of people with disabilities in mind, thus resulting in inaccessible systems. By developing a disability-aware mentality, designers of information systems can develop products that are both usable and accessible not only to people with disabilities, but to everyone.

This article has proposed a disability-aware approach to information systems design and development and shown with application to learning systems that this is what students with disabilities want and recommend such thought processes during design and development.

KEY TERMS AND DEFINITIONS

Accessibility: The design of information systems such that they can be used by everyone, regardless of their ability or disability.

Assistive Listening Device: This is a device which helps to improve hearing for people with hearing impairment.

Assistive Technology: A piece of software or device that allows a person with disability to interact with an information system without difficulty.

Disability: A physical or mental condition that may limit an individual's ability to fully utilize their senses such as vision and hearing and could thus limit their use of information systems, particularly when they are not designed accessibly.

Disability-Aware Information System: Information system that considers the needs of users with disabilities and adjusts to their needs without them having to seek extra assistive technology in order to interact with it.

Induction Loop: Also known as hearing loop, this is an assistive listening device which works by amplifying sound for an individual who can only hear partially and may not be able to distinguish speech when there is noise.

Mentality: A mindset or way of thinking. In this case, the mindset that designers of information systems should adopt in order to develop accessible and usable systems.

Subtitles: These are texts displayed in a video usually serving as a translation of the words spoken

in the video into another language so that people who don't understand the language of the video could understand what it is all about.

Transcript: In the context of this chapter, it is a text version of a video that is produced for an individual with hearing impairment, to facilitate understanding of the words spoken in the video.

Usability: This refers to how easy it is for an end user to use an information system.

Big Data

Adapting Big Data Ecosystem for Landscape of Real World Applications

Jyotsna Talreja Wassan
University of Delhi, India

INTRODUCTION

Big data is revolutionizing world in the age of Internet. The wide variety of areas like online businesses, electronic health management, social networking, demographics, geographic information systems, online education etc. are gaining insight from *big data principles*. Big data is comprised of heterogeneous datasets which are too large to be handled by traditional relational database systems. An important reason for explosion of interest in big data is that it has become cheap to store volumes of data and there is a major rise in computation capacity.

To extract valuable patterns from big data, one needs to choose a right platform for capturing, organizing, searching and analyzing the context of voluminous data.

Data Management systems adhering to big data, aim to add computing nodes to cater to increasing data volumes, automatic balancing of data between various nodes, and reducing the operational cost for functioning of distributing data over various nodes (Patel, 2016).

Various NoSQL data stores like Cassandra, MongoDB and Hadoop HBASE etc. are in use today to acquire, manage, store and query big data. NoSQL databases are inherently schema-less and permit records to have variable number of fields, making them distinct from other non-relational databases like hierarchical databases and object-oriented databases. These are highly scalable and well suited for dynamic data structures. NoSQL data is characterized by being basically available and eventually consistent.

The frameworks like MapReduce, Dryad etc. support processing of large amounts of data in parallel and hence the management of big data (Singh & Reddy, 2015). The technologies like GNU R and Apache MAHOUT are useful in exploring and analyzing big data for finding relevant valuable patterns. This article aims at giving an overview of Big Data Ecosystem comprising various big data platforms useful in today's competitive world.

BACKGROUND

In 1970's big meant megabytes, subsequently with the increasing data needs, it grew to gigabytes and terabytes and further to zettabytes with the increase in digital information. The traditional world of relational database systems like Oracle RDBMS etc. faced challenges in storing large quantities of data and needed to scale databases to data volumes beyond the storage and/or processing capabilities of a single large computer system. Many efforts have been made to store and manage data being generated from everywhere on the web. Several database management systems were proposed on the basis of master/slave, cluster computing or partitioning architecture like IBM DB2 partitioning, VoltTB etc.

However, the problems in reliance on shared facilities and resources (CPU, Disk, and Processors), scalability and complex administration limitations, augmented by lack of support for critical requirements, led to development of SHARED NOTHING architectures (Strauch, 2011; Lee, 2011) in 1980's. These systems focused on paral-

lel and distributed data computation and solved big data problems using parallel computations. By 90's, even these solutions faced challenges in running OLTP and queries due to data overload. To provide solutions to these problems, Google responded with its GFS (Dean & Ghemawat, 2004), followed by a powerful programming paradigm of MapReduce (Dean & Ghemawat, 2004). Thereafter a spectrum of new technologies emerged as the NoSQL movement stating a broad class of database management system to support increasing data storage and analytical requirements.

MAIN FOCUS

Major real world applications like health care, business analytics etc., operational on big data, cannot store or process all of the data on just one machine. The data must be stored, distributed or processed in parallel manner for computations to be completed efficiently. Various platforms are making *big data* management and processing more effective, forming the basis of current research theme in the era of *Big Data* (Gandomi & Haider, 2015). The main focus of this article is to discuss about NoSql Movement, big data platforms which could support processing of futuristic massive volumes of data in parallel and their applications.

BIG DATA ECOSYSTEM

Big data could be visualized in two aspects:

1. Big Data Storage and
2. Big Data Analytics.

Hence, Big data applications fall under two general categories:

1. Large-volume applications needing hundreds of terabytes of data to work on, or
2. Performance-intensive big data analytics applications needing computation.

Broadly big data ecosystem comprise of stacked layers of Storage (NoSQL stores), MapReduce and Query (SMAQ) as illustrated in Figure 1. SMAQ structured systems are typically open source and distributed. These systems are changing the landscape of big data processing to a broader class of users similarly as LAMP stack of Linux, Apache, MySQL and PHP changed the horizon of developing web applications (Dumbill, E., 2010).

The base idea is to store big data in parallel NoSQL data stores like MongoDB, Apache HBASE, and BigTable etc.

Above the storage layer, a layer is required to divide the stored big data set, and run it in parallel over many machine nodes. This distribution provides a solution to the issue of data being too

Figure 1. SMAQ stack for big data

Table 1. Features of NoSQL databases

Feature of NoSQL	Description
Schema-less	Database “Tables” don’t have a pre-defined schema. Records can have variable number of fields and record contents and semantics are enforced by concerned applications.
Shared nothing architecture	Each server uses its own local storage instead of available common storage pool. Thus storage is accessed at local disk speeds instead of network speeds, and this permits capacity to be enhanced by adding more number of nodes.
Sharding	It is a type database partitioning that supports horizontal partitioning of data records in smaller, faster and easily manageable shards to achieve high levels of scalability. An existing shard splits when it gets too much loaded with data. Applications can assist in data sharding by assigning each record a partition key ID
Asynchronous replication	NoSQL databases employ asynchronous replication to scale up horizontally, to become highly available and to complete processing more quickly as they don’t depend on extra network traffic. This corresponds traditionally to RAID storage or synchronous replication.
Follows CAP & BASE instead of ACID	The major characteristics common amongst NoSQL databases, working over distributed environment are: Consistency , Availability and Partition Tolerance . Eric Brewer, a professor at the University of California, Berkeley, and amongst the founders of Google, in 2001, introduced the idea that there is a fundamental trade-off between consistency, availability, and partition tolerance when considering a distributed environment and came up the CAP-theorem, which is widely adopted today in the NoSQL community (E. A. Brewer, 2000 ; S. Gilbert et al., 2002) NoSQL databases emphasize performance and availability over distributed environment. An application works basically all the time (basically available), does not have to be consistent all the time (soft-state) but will be in some known-state state eventually (eventual consistency).

large to fit onto a single machine and is commonly known as MapReduce. Many of the platforms like Hadoop, Storm, and MongoDB etc. support parallel computations through MapReduce.

SMAQ systems also incorporate a HLQL (higher-level query language) layer to simplify both the specification of the MapReduce operations and the retrieval of the result. Several of these HLQL’s like HiveQL, Pig Latin, and JAQL (Stewart, R.J. et al., 2011) etc. have emerged either as open source projects or commercial products. All of them translate higher level jobs into MapReduce jobs. HiveQL is like SQL.

NoSQL MOVEMENT FOR BIG DATA STORAGE

NoSQL movement drives through the database technology, to overcome the limitations associated with scaling and performance of traditional relational databases (RDBMS) over distributed architectures.

NoSQL stands for “Not Only SQL” or “Not Relational”. The growing needs to process continuously increasing volumes of data in lesser time, led to the movement of developing schema less data stores, parallel programming models and various analytical platforms. This movement is commonly covered under the term NoSQL. NoSQL platforms are non-relational, distributed and horizontally scalable. NoSQL platforms have been motivated by large scale web based applications, where data has to be compulsively partitioned over multiple nodes that share the load, and parallelism is essential. This section aims at providing an overview of several characteristics and categories of NoSQL data stores over SQL, based on data models (Stonebraker, M.,2010). NoSQL has some essential features as described in Table 1 (Cattell, R., 2011).

NoSQL Systems may characterize data models based on *Key*, *Aggregation* and *Connections* (Adiba, M., Castrejon-Castillo, J. C., Oviedo, et al, 2016). There are various kinds of NoSQL databases namely key-value store, document

Table 2. NoSQL datamodels

Type	Data Models	CRUD Operations	Description
Key	Key-Value	Create, Read, Update or Delete a record based on primary key	A <i>key-value store</i> provides one of the simplest possible data extraction base in which a user is allowed to fetch data by using the key and the store doesn't know <i>anything</i> about values. This key based approach makes read and writes operations (a simple disk access) very fast.
Aggregation	Document or Column Oriented	Create, Read, Update or Delete a entity/ record based on a specific pattern	A <i>document-oriented store</i> extends the key-value model and values are stored in a <i>structured</i> format (known as document), that the database can understand. For example, a blog post or comments stored as a document in a de-normalized way. Content applications (like Facebook, Twitter etc.) can fetch an entire blog post data with just a single query with the help of <i>document-oriented data stores</i> . A <i>column-oriented store</i> is advantageous for data warehouses as it stores its content by column rather than by row of data sets. It contains predefined columns and provides scaling and updating of data at relatively high speeds.
Connection	Graph	Create, Read, Update or Delete a record based on relationships between entities.	<i>Graph data stores</i> are built with nodes, their properties and relationships amongst them. A flexible graph model is used to scale across many machines instead of tables of rows and columns in the rigid structure of SQL

oriented store, column oriented stores and graph data stores (Russom, P., 2011).

Various examples of NoSQL databases from each of the above mentioned categories are listed in Table 3.

None amongst the above mentioned databases in Table 3 are best for all user cases. The choice of user depends on the application, as well as the type of scalability required. Thus the record semantics in these data stores are enforced by user applications (Tauro & Aravindh et al., 2012).

COMPARISION OF VARIOUS NoSQL BIG DATA PLATFOMS

Variety of NoSQL platforms are discussed in Table 4.

MAP: REDUCE PARADIGM FOR BIG DATA ANALYTICS

Map Reduce is a simple but powerful programming paradigm, used for development of scalable

Table 3. Classifications of NoSQL databases

Category	Databases
Key-Value Databases	DynamoDB, Riak, Redis, Aerospike, Azure Table Storage, FoundationDB, LevelDB, GenieDB, BangDB, Chordless, Scalaris, Tokyo, Cabinet / Tyrant, Scalien, Voldemort, Dynomite, KAI, MemcacheDB, Chordless, HamsterDB, Tarantool/Box, Maxtable, Pincaster, RaptorDB, Mnesia, LightCloud, Hibari, OpenLDAP, LSM, STSdb
Document Databases	MongoDB, Elasticsearch, Couchbase Server, CouchDB, RethinkDB, RavenDB, MarkLogic, Server, Clusterpoint Server, ThruDB, Terrastore, RaptorDB, JasDB, SisoDB, SDB, djondb, EJDB, densodb
Column Databases	Hadoop / HBase, Cassandra, Hypertable, Accumulo, Amazon SimpleDB, Cloudata, Stratosphere, Cloudera, HPCC,
Graph Databases	Neo4J, Infinite Graph, InfoGrid, HyperGraphDB, DEX, GraphBase, Trinity, AllegroGraph, BrightstarDB, Bigdata, Meronymy

Table 4. Comparison of various No-SQL databases

	<i>Riak</i>	<i>MongoDB</i>	<i>HBase</i>	<i>Cassandra</i>	<i>Neo4J</i>
Description	Riak is a distributed open source key/value store by Basho Technologies, which scales predictably and makes development easier by giving users the facility to prototype, test, and deploy their applications.	MongoDB (from “humongous”) is a NoSQL based open source document-oriented database, developed by 10Gen company. MongoDB stores structured data as JSON-like documents having dynamic schemas, facilitating the integration of data in certain types of applications easier and faster. The communication with MongoDB is done using a BSON driver in any language like Ruby, PHP etc. or using the MongoDB JavaScript shell.	HBase is the high-performance non-relational column oriented database, supporting real time and random access to Big Data stored. It was modeled after Google’s Big Table and runs over HDFS. It is under Apache licensing. It is natively integrated with Hadoop and works with other database engines through YARN. It supports master node that manages the cluster and other servers storing portions of data. It scales linearly and has the capability to easily combine data from various sources.	Cassandra is a distributed system, supported by DataStax, and was originally open sourced by Facebook in 2008. It is used under Apache licensing. Jeff Hammerbacher, who led the Facebook data team at that time, described Cassandra as a BigTable data model which uses architectural concepts introduced by Amazon Dynamo. It is a wide column store database.	Neo4j is a robust ACID transactional property graph database developed by Neo Technologies.. Neo4j is highly agile and runs a thousand times faster than relational databases for connected data operations due to its graph data model.
Data Model	Riak uses a simple key/value model for object storage. Riak contains objects in the form of a unique key and value, stored in a flat namespace known as a bucket. One can store anything in Riak including text, images, JSON/XML/HTML documents, log files etc. Data is stored and referenced by bucket/key pairs. Each key is attached to a unique value any data type.	Databases in MongoDB are the groups of collections stored on disk using a single set of data files where collections are containers for documents that share one or more indexes. Each document collection is stored in one namespace file.	HBase system consists of set of tables designed to store semi structured data that could vary in field size, data types or columns. Each table has rows representing objects and columns representing attribute of an object, like traditional databases. Each table must have an element defined as a Primary Key which is used to access the table. HBase allows for many attributes or data in a row to be grouped together into column families, such that the elements of a column family are all stored together. HBase table schema is scalable and flexible.	Cassandra data model is comprised of columns, rows, column families, and keyspace. Each column consists of a name and a value. A row is the collection of columns labeled with a same name. Each row is uniquely identifiable by a key within a column family. Each row in a column family may have a different set of columns. This indicates the schema-less model in Cassandra. A collection of columns along with the row keys forms a column family and the logical grouping of column families is known as keyspace which is used as schema.	Neo4j is an “embedded, disk-based, fully transactional Java persistence engine” that stores data structured in nodes of a graph rather than in tables of traditional RDBMS. The nodes of a graph in Neo4j are organized by relationships which also have properties. A traversal of graph is used to query a Graph, ranging from starting node to related nodes according to sequence of instructions and finding answers to the queries. An index can also be created to perform look up operations as it maps properties to either nodes or relationships.
Implementation Language	Erlang	C++	Java	Java	Java
Technical Details Available on	docs.basho.com	docs.mongodb.org/manual	hbase.apache.org	www.datastax.com/docs	neo4j.com/docs/stable
Supports Map-Reduce	Yes	Yes	Yes	Yes	No
Replication	Selectable Replication Factor	Master- Slave	Selectable Replication Factor	Selectable Replication Factor	Master- Slave
Support for Server Side Scripts	Java Script & Erlang	Java Script	Yes	No	Yes
Partitioning	Sharding	Sharding	Sharding	Sharding	No

applications. It handles the computation in terms of a *Map* and a *Reduce* functions (Dean & Ghemawat, 2004).

Map Function: Takes an input pair and produces a set of intermediate key/value pairs e.g.,

- **Map:** $(key_1, value_1) \rightarrow \text{list of } (key_2, value_2)$.

The MapReduce library groups together all intermediate values associated with the same intermediate key

- **Reduce Function:** Accepts an intermediate key and a set of values for that key.
- **Reduce:** $(key_2, \text{list of } (key_2, value_2)) \rightarrow value_3$.

The underlying runtime system automatically parallelizes the computation across large-scale clusters of computing nodes via automatic load balancing. (Dean, & Ghemawat, 2004).

The MapReduce paradigm could be applied to various areas. To better understand the MapReduce, the following example is illustrated.

Problem Statement

To determine the count of each word that appears in a file/document (or a set of documents). Each file is associated with a document URL/ID.

- **Motivation:** Various real world applications are based on counting and summing problems. E.g. there is a log file where each record contains a URL and it is required to calculate frequency of websites accessed.

Solution

- **Map Function:** Input to map functions is: **Key** = document URL/ID; **Value** = document contents. Outputs of map function are (potentially many) key/value pairs. Output (word, "1") once per word in the document

- **Pseudo Code for Map - Map (String key, String value):** // input key: document name, input value: document contents.

For each word w in value:

Emit Intermediate (w, "1");

- **Example: Key, Value Pair:** "documentID01", "he is a dictator or he is a narrator"

Result of applying the above map function is:

```
"he", 1
"is", 1
"a", 1
"dictator", 1
"he", 1
"is", 1
"a", 1
"narrator", 1
```

Pseudo-Code for Reduce

- **Reduce (String Key, Values):** // key: a word, same for input and output; values: a list of counts

```
int result = 0;
```

For each v in values:

```
Result = Result + value;
```

```
Emit (Result);
```

The function sums together all counts emitted for a particular word. The MapReduce framework sorts all pairs with the same key

(a,1), (a,1), (he, 1), (he,1), (is,1), (is,1), (narrator, 1), (or, 1), (dictator,1)

The pairs are then grouped as: (a, 1, 1), (he, 1, 1), (is,1, 1), (or, 1), (narrator, 1),(dictator,1)

The reduce function combines (sums) the values for a key.

Figure 2. Illustration of an example of MapReduce

- **Example:** Applying reduce to (a, 1, 1) gives value as 2. The scenario could be realized as illustrated in Figure 2.

Various applications where MapReduce could be applied are:

- Log Querying and Analysis,
- Geospatial Query Processing,
- Page Rank Algorithms,
- Engineering Simulations,
- Graph Processing,
- Processing Health Care Records (EHRs),
- Relational patterns like joins, projection, union, intersection etc.,
- Machine learning applications like linear regressions,
- k means, neural networks etc., and
- Mathematical Problems like Sparse Matrix operations on large data.

And the list goes on with advancements in distributed environment.

There are scenarios, where MapReduce programming model cannot be employed.

For example, if the output of the computation depends on previously computed values, then MapReduce cannot be used. Fibonacci series calculation where each value is summation of the previous two values: $\text{fib}(k+2) = \text{fib}(k+1) + \text{fib}(k)$, is one of the classic example of this scenario.

Map reduce is maturing to handle complex areas like real time streaming data, XML query processing etc in various platforms.

EMERGING APPLICATIONS OF BIG DATA PLATFORMS

Big Data movement with NoSQL platforms, has become imperative for various industries and these are using big data in variety of contexts (Boinepelli, 2015). NoSQL platforms could be

1. Chosen to develop new applications (cloud based).
2. Chosen to modify an existing (RDBMS) system by augmenting NoSQL platform for making the existing relational system scalable.

Figure 3. Big data and social networks intersection

3. Chosen to replace existing system to fulfill the needs of volume, variety, velocity in data.

In *Internet of things*, NoSQL has emerged as the preferred choice for various applications such as Web Development, Social Networks, Health Sector, Mobile Apps, Education etc (Lohr, S., 2012).

Big Data in Health Care

Healthcare is influenced by various challenges, like high-rising expenditures, inconsistent quality, and delays in care and access in various areas across the world. It is important to improve health care quality and it is widely believed that the use of information technology in health care is aiding in reducing the cost of health care while improving its quality. Especially electronic health records (EHRs), have been thought to be possible solutions to these problems as they store all the information about a patient and make it interoperable and shared among different health care providers. EHRs deal with heterogeneous, volumetric and may time real time data. To deal with this, Healthcare is undergoing the Big Data Revolution (Wassan, 2015). In parallel, advancement in techniques using big data platforms, have made it easier to collect and analyze heterogeneous health data from multiple sources like patients, hospitals, laboratories, and physicians and insurance payors. Big Data interventions have brought about a 300-450

billion dollar reduction in U.S. healthcare (<http://rockhealth.com>). The true potential of digitized information lies in big data handling in EHRs providing structured output. EHRs using big data techniques aim to play a major part in the health-care reforms and health records could be mined to detect fruitful health related patterns using big data analytics tools and techniques.

Big Data in Social Networks

Social networking and media applications containing human communication and interaction also generate large amounts of data whose processing scales out with the use of high performance servers, data mining grids and usage of platforms like Hadoop and parallel modeling paradigms like MapReduce to enhance the computation and storage performance (Figure 3).

Social media providers focus not only on measuring followers, friends and likes on social networking sites like Facebook and Twitter, but also on analyzing and integrating the emerging volumes of data into future business strategies deriving insight for enhancing business intelligence. Web search engines and social networks capture and analyze every user action on their sites to improve site features, generating recommendations for the visitors, spam and fraud detection, and advertising opportunities. This could be analysed efficiently by using big data platforms.

Figure 4. Big data approaching online business trends

Big Data in Education

Big data may also has great impact on the education field like it is impacting other sectors such as social media and medicines. The big data technology also offers a great platform for the authorities looking to improve their educational institutions. Educational institutions are also generating huge volumes of data, from grades or test scores to admissions or enrollment numbers while in-taking students in an institution.

With the advent of online courses offered by many universities, the amount of data available to educational officials and students has exploded. The development of electronic learning courses enable learning and assessment of students in systematic, real-time ways and big data platforms could be fruitful in handling the educational data streams (Wassan, 2015).

Many universities across the world ; have an eAdvisor system in which a candidate can choose amongst broad areas of study to facilitate learning and in identifying study areas of interests. (Parry, 2012). A number of educational institutions have developed dashboard software to monitor learning, performance, and behavioral issues for individual students as well as the school as a whole (West, 2012). All these softwares could be enhanced with Big Data techniques to handle large amounts of educational data.

Big Data in Online Retailing Business

Today more and more online retailers are interacting with their customers in real time. The retail sector has witnessed strong demands and returns on investment in an online environment. The ability to analyze and predict consumer behavior on the basis of patterns mined from stored transactional data; has proved to be an invaluable tool for retailers looking to engage customers and gain an edge over competitors (Figure 4).

With the huge volumes of customer data, online retailers tend to benefit from predictive analytics applications. Various big data applications designed on the Hadoop, Cloudera etc. platforms, can provide businesses with tools that may prove more useful for enhancing customer and retailer relationship. E-Commerce retailers can more effectively manage their resources with the big data solutions. Big data analytics is proving highly useful for online retailers.

RECOMMENDATIONS

Choosing Right Big Data Platform w.r.t to Application Needs

Big Data platform choice is impacted by an architecture (e.g. distributed, clustered machines)

for storing the data and programming models for development of data parallel, distributed applications for big data considering factors like scalability limits, query speed etc. It demands cost effectiveness and real time support for data.

Design Models for Security w.r.t Big Data Analytics

Big data analytics also requires governance, privacy, and security.

FUTURE RESEARCH DIRECTIONS

The scope of big data varies widely. The techniques for storage, management and analysis of big data are still emerging with day to day changing trends in volume, velocity and variety of data.

The continuous efforts taken for building timely and cost-effective management over “Big Data” are appreciable and will form the basis of key ingredient for success in many disciplines. We must aim for designing of efficient applications or their updation to handle big data needs by using big data platforms and gaining insight of their usage.

Also there is a need for building highly scalable comprehensive BDMS (Big Data Management Software) like RDBMS. Asterix, is one such example and is expanding its work in three areas: semi structured data, parallel database systems, and data-intensive computing (Borkar, V.R. & Carey, M.J., et al., 2012). Asterix could be explored as a comprehensive suite.

CONCLUSION

The article focuses on big data revolution i.e. changing trends in data w.r.t size and its structure and Big Data Ecosystem (SMAQ) supporting the same. It focuses on NoSQL movement with various NoSQL databases and their applications in

real world. It listed MapReduce and applications of Big Data in real world.

To conclude, it provides an idea that big data field is emerging and we need to think and query about everything in relation to big data storage, management and analysis. It may involve multi-user, multi-dimensional, heterogeneous data environment having queries of widely varying needs, importance and sizes. Big data platforms must learn to manage such workloads effectively by developing or exploring whole Big Data Management Systems (BDMS)..

KEY TERMS AND DEFINITIONS

Big Data: A term that describes large amount of data that could be structured, unstructured or real time and is difficult to be handled by traditional systems. It is identified by major 3 V's: Volume, Variety and Velocity.

Data Intensive Computing: It classifies various parallel computing applications which use a data parallel approach to process large volumes of data like terabytes or petabytes in size and referred to as Big Data.

Database Management Systems (DBMS): A Database Management Systems (DBMS) is a set of programs that enables storing, adding, deleting, accessing, modifying, updating or analyzing data stored in one location.

Distributed System: It consists of autonomous machine nodes connected in a network to communicate, share and coordinate their activities through message passing to achieve a common goal.

MapReduce: MapReduce is a parallel programming model proposed by Google and is used to distribute computing on clusters of computers for processing large data sets.

Online Transaction Processing (OLTP): It refers to a class of systems that facilitate and manage transaction-oriented applications, typically for data entry and retrieval transaction processing.

B

Big Data Analysis and Mining

Carson K. Leung

University of Manitoba, Canada

INTRODUCTION

Advancements in the field of information science and technology enables users to collect or generate high volumes of valuable data of different levels of veracities—such as streams of banking, financial, and shopper market basket data—at high velocities from wide varieties of data source in various real-life business, engineering, scientific applications in modern organizations and society. Embedded in these *big data* (Madden, 2012; Leung, 2015) is implicit, previously unknown, and potentially useful information and knowledge. However, these big data come with volumes beyond the ability of commonly-used software to capture, manage, and process within a tolerable elapsed time. Hence, new forms of information science and technology—such as *big data analysis and mining*—are needed to process and analyze these big data so to as enable enhanced decision making, insight, knowledge discovery, and process optimization. Over the past few years, algorithms have been proposed for various big data analysis and mining tasks, including clustering (which groups similar data together), classification (which categorizes groups of similar data), outlier detection (which identifies anomalies), and frequent pattern mining (which discovers interesting knowledge in the forms of frequently occurring sets of merchandise items or events). Most of these algorithms use the *MapReduce* model—which mines the search space with distributed or parallel computing (Shim, 2012). Among different big data analysis and mining tasks, this chapter focuses on applying the MapReduce model to big data for the discovery of frequent patterns.

BACKGROUND

Since the introduction of the research problem of *frequent pattern mining* (Agrawal, Imieliński, & Swami, 1993), numerous algorithms have been proposed (Hipp, Güntzer, & Nakhaeizadeh, 2000; Ullman, 2000; Ceglar & Roddick, 2006). Notable ones include the classical Apriori algorithm (Agrawal & Srikant, 1994) and its variants such as the Partition algorithm (Savasere, Omiecinski, & Navathe, 1995). The Apriori algorithm uses a level-wise breadth-first bottom-up approach with a candidate generate-and-test paradigm to mine frequent patterns from transactional databases of precise data. The Partition algorithm divides the databases into several partitions and applies the Apriori algorithm to each partition to obtain patterns that are locally frequent in the partition. As being locally frequent is a necessary condition for a pattern to be globally frequent, these locally frequent patterns are tested to see if they are globally frequent in the databases. To avoid the candidate generate-and-test paradigm, the tree-based FP-growth algorithm (Han, Pei, & Yin, 2000) was proposed. It uses a depth-first pattern-growth (i.e., divide-and-conquer) approach to mine frequent patterns using a tree structure that captures the contents of the databases. Specifically, the algorithm recursively extracts appropriate tree paths to form projected databases containing relevant transactions and to discover frequent patterns from these projected databases.

In various real-life business, engineering, scientific applications in modern organizations and society, the available data are not *precise* data but *uncertain* data (Tong et al., 2012; Leung,

Cuzzocrea, & Jiang, 2013; Leung, MacKinnon & Tanbeer, 2014; Jiang & Leung, 2015; Ahmed et al., 2016). Examples include sensor data and privacy-preserving data. Over the past few years, several algorithms have been proposed to mine and analyze these uncertain data. The tree-based UF-growth algorithm (Leung, Mateo, & Brajczuk, 2008) is an example.

With high volumes of big data, it is not unusual for users to have some phenomenon in mind. For example, a store manager is interested in some promotional items. Hence, it would be more desirable if data mining algorithms return only those patterns containing the promotional items rather than returning all frequent patterns, out of which many may be uninteresting to the store manager. It leads to *constrained mining*, in which users can express their interests by specifying constraints and the mining algorithm can reduce the computational effort by focusing on mining those patterns that are interesting to the users.

Besides the aforementioned algorithms discover frequent patterns *in serial*, there are also *parallel and distributed* frequent pattern mining algorithms (Zaki, 1999). For example, the Count Distribution algorithm (Agrawal & Shafer, 1996) is a parallelization of the Apriori algorithm. It divides transactional databases of precise data and assigns them to parallel processors. Each processor counts the frequency of patterns assigned to it and exchanges this frequency information with other processors. This counting and information exchange process is repeated for each pass/database scan.

As we are moving into the new era of big data, more efficient mining algorithms are needed because these data are wide varieties of valuable data of different veracities with volumes beyond the ability of commonly-used algorithms for mining and analyzing within a tolerable elapsed time. To handle big data, researchers proposed the use of the *MapReduce programming model*.

BIG DATA ANALYSIS AND MINING FOR FREQUENT PATTERNS

B

The MapReduce Programming Model

MapReduce (Dean & Ghemawat, 2004; Dean & Ghemawat, 2010) is a high-level programming model for processing high volumes of data. It uses parallel and distributed computing on large clusters or grids of nodes (i.e., commodity machines), which consist of a master node and multiple worker nodes. As implied by its name, MapReduce involves two key functions:

1. The “map” function, and
2. The “reduce” function.

To solve a problem using MapReduce, the master node reads and divides input big data into several partitions (sub-problems), and then assigns them to different worker nodes. Each worker node executes the *map function* on each partition (sub-problem). The map function takes a pair of $\langle \text{key}, \text{value} \rangle$ and returns a list of $\langle \text{key}, \text{value} \rangle$ pairs as an intermediate result:

- **Map:** $\langle \text{key}_1, \text{value}_1 \rangle \mapsto \text{list of } \langle \text{key}_2, \text{value}_2 \rangle$,

where:

1. key_1 & key_2 are keys in the same or different domains, and
2. value_1 & value_2 are the corresponding values in some domains.

The pairs in the list of $\langle \text{key}, \text{value} \rangle$ pairs for this intermediate result are then shuffled and sorted. Each worker node then executes the *reduce function* on:

1. A single key from this intermediate result, and
2. The list of all values that appear with this key in the intermediate result.

The reduce function “reduces”—by combining, aggregating, summarizing, filtering, and/or transforming—the list of values associated with a given key (for all k keys) in worker nodes and returns a list of $\langle \text{key}, \text{value} \rangle$ pairs, a list of values, or simply a single (aggregated or summarized) value:

- **Reduce:** $\langle \text{key}_2, \text{list of value}_2 \rangle \mapsto \text{list of } \langle \text{key}_3, \text{value}_3 \rangle$, or list of value_3 , or a single value_3 ,

where:

1. key_2 & key_3 are keys in some domains, and
2. value_2 & value_3 are the corresponding values in some domains.

By using the MapReduce model, users only need to focus on (and specify) the map and reduce functions, without worrying about implementation details for partitioning the input data, scheduling and executing the program across multiple machines, handling machine failures, or managing inter-machine communication.

Earlier works on MapReduce mainly focused on data processing in big databases (Dean & Ghemawat, 2004) or some big data mining tasks other than frequent pattern mining. Examples of big data processing with MapReduce include the construction of inverted indexes, the evaluation of queries involving joins or selection, the elimination of duplicates, text processing tasks (Lin & Dyer, 2010; Jiang & Leung, 2015) like the word counting of documents, and the processing of data cubes (Lee & Kim, 2016). Examples of big data mining with MapReduce include clustering (Shahrivari & Jalili, 2016), classification (Bechini, Marcelloni, & Segatori, 2016), and outlier detection (Liao & Squicciarini, 2015).

Apriori-Based MapReduce Algorithms: SPC, FPC, and DPC

To mine frequent patterns from big databases of precise data with MapReduce, Lin et al. (2012)

proposed three algorithms—namely, the Single Pass Counting (SPC), Fixed Passes Combined-counting (FPC), and Dynamic Passes Combined-counting (DPC) algorithms—based on both the Apriori and the Count Distribution algorithms. SPC first divides the databases into partitions, and then executes map and reduce functions in each pass k to generate candidate k -itemsets (i.e., candidate patterns each consisting of k items) and count their support/frequency. More specifically, SPC executes the following map and reduce functions in Pass 1:

- **Map:** $\langle \text{ID of transaction } t_j \in \text{partition } P_i, \text{contents of } t_j \rangle \mapsto \text{list of } \langle \text{item } x \in t_j, 1 \rangle$, and
- **Reduce:** $\langle x, \text{list of 1's} \rangle \mapsto \text{list of } \langle \text{frequent 1-itemset } \{x\}, \text{sup}(\{x\}) = \text{sum of 1's in the list for } x \rangle$.

Here, the worker node corresponding to each partition P_i of the big databases executes the map function by outputting $\langle x, 1 \rangle$ (which represents the support of candidate 1-itemset $\{x\}$ in $t_j = 1$) for every item x in transaction $t_j \in P_i$:

For each transaction $t_j \in \text{partition } P_i$ **do**
 for each item $x \in t_j$ **do**
 output $\langle x, 1 \rangle$.

The reduce function is then executed by summing all the 1's for each x to compute its support $\text{sup}(\{x\})$, and outputting $\langle \{x\}, \text{sup}(\{x\}) \rangle$ (which represents a frequent 1-itemset $\{x\}$ and its frequency) if $\text{sup}(\{x\}) \geq$ a user-specific *minsup* threshold:

For each $x \in \langle x, \text{list of 1's} \rangle$ **do**
 $\text{sup}(\{x\}) = \text{sum of 1's in the list for } x$
 if $\text{sup}(\{x\}) \geq \text{minsup}$
 then output $\langle \{x\}, \text{sup}(\{x\}) \rangle$.

In each subsequent pass $k \geq 2$, SPC generates candidate k -itemsets from frequent $(k-1)$ -itemsets. The worker node corresponding to each partition P_i then outputs $\langle X, 1 \rangle$ for every candidate

k -itemset X that exists in some transaction $t_j \in P_i$. Afterwards, the reduce function sums all the 1's for each X to compute its support $sup(X)$, and output $\langle X, sup(X) \rangle$ (which represents a frequent k -itemset X and its frequency) if $sup(X) \geq minsup$. In other words, SPC executes the following map and reduce functions in Pass k (for every $k \geq 2$):

- **Map:** $\langle \text{ID of } t_j \in P_i, \text{contents of } t_j \rangle \mapsto \text{list of } \langle \text{candidate } k\text{-itemset } X \subseteq t_j, 1 \rangle, \text{ and}$
- **Reduce:** $\langle X, \text{list of } 1\text{'s} \rangle \mapsto \text{list of } \langle \text{frequent } k\text{-itemset } X, sup(X) = \text{sum of } 1\text{'s in the list for } X \rangle$.

The three algorithms (SPC, FPC and DPC) are similar except that both FPC and DPC apply the *pass bundling* technique to reduce the number of passes/database scans in each P_i when generating candidate itemsets (for Pass $k \geq 3$). For instance, FPC statistically bundles a fixed number of passes (e.g., three passes) to generate all candidate k -, $(k+1)$ -, and $(k+2)$ -itemsets from frequent $(k-1)$ -itemsets. In contrast, DPC dynamically bundles several passes (depending on the number of generated candidates in these bundled passes).

Partition-Based MapReduce Algorithm

On the one hand, the use of the pass bundling technique reduces the number of passes/database scans in each partition P_i . On the other hand, the Apriori-based SPC, FPC and DPC algorithms still require multiple passes/database scans when mining frequent patterns from big data. In contrast, the MapReduce version of the Partition algorithm—presented by Rajaraman & Ullman (2011)—requires only two passes/database scans. Hence, the Partition-based MapReduce algorithm uses two sets of “map” and “reduce” functions. Specifically, the master node reads and divides big databases of precise data into partitions. The worker node corresponding to each partition P_i then outputs $\langle X, 1 \rangle$ for every candidate pattern X (of any cardinality) that exists in some transaction $t_j \in P_i$. The reduce function then sums all

the 1's for each X to find patterns that are locally frequent in P_i . Taking the union of these locally frequent patterns forms global candidate patterns. To summarize, the first set of “map” and “reduce” functions can be expressed as follows:

- **Map:** $\langle \text{ID of transaction } t_j \in P_i, \text{contents of } t_j \rangle \mapsto \text{list of } \langle \text{itemset } X \subseteq t_j, 1 \rangle, \text{ and}$
- **Reduce:** $\langle X, \text{list of } 1\text{'s} \rangle \mapsto \text{list of } \langle \text{locally frequent itemset } X, \text{NULL} \rangle$.

Afterwards, the worker node corresponding to each partition P_i outputs $\langle X, 1 \rangle$ for every global candidate pattern X that exists in some transaction $t_j \in P_i$. Then, the reduce function sums all the 1's for each X to compute its support $sup(X)$, and outputs $\langle X, sup(X) \rangle$ (which represents a globally frequent pattern X and its frequency) if $sup(X) \geq minsup$. To summarize, the second set of “map” and “reduce” functions can be expressed as follows:

- **Map:** $\langle \text{ID of } t_j \in P_i, \text{contents of } t_j \rangle \mapsto \text{list of } \langle \text{global candidate pattern } X \subseteq t_j, 1 \rangle, \text{ and}$
- **Reduce:** $\langle X, \text{list of } 1\text{'s} \rangle \mapsto \text{list of } \langle \text{globally frequent pattern } X, sup(X) \rangle$.

Tree-Based MapReduce Algorithm for Precise Data: PFP

Given that tree-based algorithms avoid the candidate generate-and-test paradigm of Apriori-based algorithms, Li et al. (2008) proposed the Parallel FP-growth (PFP) algorithm for query recommendation. PFP uses MapReduce to parallelize the tree-based FP-growth algorithm by first reading and dividing big databases of precise data into several partitions. The worker node corresponding to each partition P_i then outputs $\langle \{x\}, 1 \rangle$ for every item x in transaction $t_j \in P_i$. The reduce function then sums all the 1's for each x to compute its support $sup(\{x\})$, and outputs $\langle \{x\}, sup(\{x\}) \rangle$ (which represents a frequent 1-itemset $\{x\}$ and its frequency) if $sup(\{x\}) \geq minsup$. In other words, PFP first executes the following set of “map” and “reduce” functions:

- **Map:** $\langle \text{ID of transaction } t_j \in \text{database partition } P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \text{item } x \in t_j, 1 \rangle$, and
- **Reduce:** $\langle x, \text{list of 1's} \rangle \mapsto \text{list of } \langle \text{frequent 1-itemset } \{x\}, \text{sup}(\{x\}) = \text{sum of 1's in the list for } x \rangle$.

Afterwards, PFP reads the big databases a second time to form an $\{x\}$ -projected database (i.e., a collection of transactions containing x) for each item x in the list produced from the first reduce function (i.e., for each frequent 1-itemset $\{x\}$). The worker node corresponding to each projected database then:

1. Builds appropriate local FP-trees (based on the projected database assigned to the node) to mine frequent k -itemsets (for $k \geq 2$), and
2. Outputs $\langle X, \text{sup}(X) \rangle$ (which represents a frequent k -itemset X and its frequency) if $\text{sup}(X) \geq \text{minsup}$.

To summarize, PFP executes the second set of “map” and “reduce” functions as follows:

- **Map:** $\langle \text{ID of transaction } t_j \in P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \{x\}, \{x\}\text{-projected database} \rangle$, and
- **Reduce:** $\langle \{x\}, \{x\}\text{-projected database} \rangle \mapsto \text{list of } \langle \text{frequent itemset } X, \text{sup}(X) \rangle$.

As PFP was designed for query recommendation, it usually takes a third set of “map” and “reduce” functions to aggregate and rank the list of frequent itemsets for the top-K frequent patterns to facilitate recommendations.

Tree-Based MapReduce Algorithm for Uncertain Data: MR-growth

Characteristics of big data can be described by the 5Vs: volume, value, velocity, variety, and veracity. Among the 5Vs, veracity focuses on the quality of data (e.g., precision, uncertainty, messiness, or trustworthiness of data). In many

real-life applications, available data can be *uncertain*. Uncertainty of the data may partially be caused by various factors such as imprecision or limitation of measuring instruments, as well as intentional blurring of data for privacy-preserving data. Hence, in these applications, users may be uncertain about the presence or absence of some merchandise items or events. For example, a manager may highly suspect (but cannot guarantee) that a customer is interested in certain products without explicitly asking the customer. The uncertainty of such suspicion can be expressed in terms of existential probability. Hence, to handle uncertain data, each item x in the transaction t_j is associated with an existential probability $P(x, t_j)$ expressing the likelihood of the presence of that item or event. With this notion, each item in a transactional database of precise data can be viewed as an item with a 100% likelihood of being present in the transaction.

When using probabilistic-based mining with the “possible world” interpretation (Leung, 2013; Leung, 2014), a pattern is considered *frequent* if its expected support is no less than the user-specified *minsup* threshold. When items within a pattern X are independent, the *expected support* of X in the database can be computed by summing (over all transactions) the product (of existential probabilities within X):

$$\text{expSup}(X) = \sum_{t_j} (\prod_{x \in X} P(x, t_j))$$

where $P(x, t_j)$ is the existential probability of item x in transaction t_j .

Leung & Hayduk (2013) presented the MR-growth algorithm, which uses MapReduce to mine frequent patterns from *uncertain* data in a tree-based pattern-growth fashion for big data mining. Again, MR-growth uses two sets of the “map” and “reduce” functions. Specifically, the master node reads and divides uncertain data into partitions. The worker node corresponding to each partition P_i then outputs $\langle \{x\}, P(x, t_j) \rangle$ for every item x in transaction $t_j \in P_i$. Note that, unlike the map functions for the aforementioned algorithms

(which output $\langle \{x\}, 1 \rangle$ for representing the actual support of x in $t_j = 1$, i.e., x appears 1 time in t_j), the map function for MR-growth outputs $\langle \{x\}, P(x, t_j) \rangle$ (where $P(x, t_j)$ indicates the expected support of x in t_j , which means x has a probability of $P(x, t_j)$ to appear in t_j):

- **Map:** $\langle \text{ID of transaction } t_j \in \text{database partition } P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \text{item } x \in t_j, P(x, t_j) \rangle$.

Then, the reduce function sums all the $P(x, t_j)$'s for each x to compute its expected support $\text{expSup}(\{x\})$, and outputs $\langle \{x\}, \text{expSup}(\{x\}) \rangle$ (representing a frequent 1-itemset $\{x\}$ and its expected support) if $\text{expSup}(\{x\}) \geq \text{minsup}$:

- **Reduce:** $\langle x, \text{list of } P(x, t_j)\text{'s} \rangle \mapsto \text{list of } \langle \text{frequent 1-itemset } \{x\}, \text{expSup}(\{x\}) \rangle$.

where $\text{expSup}(\{x\}) = \text{sum of } P(x, t_j) \text{ in the list for } x$. Notice that, when handling precise data, the actual support of $\{x\}$ is its frequency. In contrast, when handling uncertain data, the expected support of $\{x\}$ may not be the same as its frequency. For instance, consider an item b with existential probability of 0.9 that appears only in transaction t_1 . Its expected support may be higher than item c that appears seven times but with an existential probability of 0.1 in each appearance. Then, $\text{expSup}(\{b\}) = 0.9 > 0.7 = \text{expSup}(\{c\})$.

Afterwards, MR-growth rereads the big databases to form an $\{x\}$ -projected database (i.e., a collection of transactions containing x) for each item x in the list produced from the first reduce function (i.e., for each frequent 1-itemset x). The worker node corresponding to each projected database then:

1. Builds appropriate local UF-trees (based on the projected database assigned to the node) to mine frequent k -itemsets (for $k \geq 2$), and
2. Outputs $\langle X, \text{expSup}(X) \rangle$ (which represents a frequent k -itemset X and its expected support) if $\text{expSup}(X) \geq \text{minsup}$.

To summarize, MR-growth executes the second set of “map” and “reduce” functions as follows:

- **Map:** $\langle \text{ID of transaction } t_j \in P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \{x\}, \{x\}\text{-projected database} \rangle$, and
- **Reduce:** $\langle \{x\}, \{x\}\text{-projected database} \rangle \mapsto \text{list of } \langle \text{frequent itemset } X, \text{expSup}(X) \rangle$.

Constraint-Based MapReduce Algorithm: BigAnt and BigSAM

When mining and analyzing high-volume big data, it is not uncommon that users may be interested in only some subsets of these big data in many real-life situations. This leads to *constraint-based mining* (Bonchi, 2009; Leung, 2009), with which users can focus the mining on certain subsets of the big data by freely specifying some constraints to express their interest. For example, users can express their interests in finding a collection X of meteorological records having a total rainfall of less than 10mm by specifying a constraint “ $\text{sum}(X.\text{Rainfall}) < 10\text{mm}$ ”. Similarly users can also express their interests in finding a collection Y of geographic records with a minimum GPS coordinate (latitude) of 45°N by specifying a constraint “ $\text{min}(Y.\text{GPSCoordinate}) = 45^\circ\text{N}$ ”.

To handle these constraints and to focus the mining on those subsets of big data that are interesting to users, Leung & Jiang (2014) proposed the BigAnt algorithm to handle the user-specified anti-monotonic constraints by exploring the anti-monotonicity of the constraints, which states that “if a pattern satisfies an anti-monotonic constraint, then so do all its subsets”. In other words, if a pattern violates the anti-monotonic constraints, it can be pruned as any of its supersets is guaranteed to violate the constraints. For instance, if $\text{sum}(Z.\text{Rainfall}) \geq 10\text{mm}$ for some pattern Z , then $\text{sum}(Z'.\text{Rainfall}) \geq 10\text{mm}$ for any superset Z' of Z . So, the BigAnt algorithm also uses two sets of the “map” and “reduce” functions. The master node reads and divides uncertain data into partitions. The worker node corresponding to each partition

P_i then performs constraint checking and outputs $\langle \{x\}, P(x, t_j) \rangle$ for every *valid* item x in transaction $t_j \in P_i$ (when $\{x\}$ satisfies the constraints):

- **Map:** $\langle \text{ID of transaction } t_j \in \text{partition } P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \text{valid item } x \in t_j, P(x, t_j) \rangle$.

Then, the reduce function sums all the $P(x, t_j)$'s for each valid x to compute its expected support $\text{expSup}(\{x\})$, and outputs $\langle \{x\}, \text{expSup}(\{x\}) \rangle$ (representing a valid frequent 1-itemset $\{x\}$ and its expected support) if $\text{expSup}(\{x\}) \geq \text{minsup}$:

- **Reduce:** $\langle \text{valid } x, \text{list of } P(x, t_j)\text{'s} \rangle \mapsto \text{list of } \langle \text{valid frequent 1-itemset } \{x\}, \text{expSup}(\{x\}) \rangle$,

where $\text{expSup}(\{x\}) = \text{sum of } P(x, t_j) \text{ in the list for } x$. Afterwards, BigAnt rereads the big databases to form an $\{x\}$ -projected database (i.e., a collection of transactions containing x) for each *valid* item x in the list produced from the first reduce function (i.e., for each valid frequent 1-itemset x). The worker node corresponding to each projected database then:

1. Builds appropriate local UF-trees (based on the projected database assigned to the node) to mine frequent k -itemsets (for $k \geq 2$),
2. Performs constraint checking to find valid ones from these mined frequent k -itemsets, and
3. Outputs $\langle \text{valid } X, \text{expSup}(X) \rangle$ (which represents a valid frequent k -itemset X and its expected support) if $\text{expSup}(X) \geq \text{minsup}$ and X is valid with respect to the user-specified constraints.

To summarize, BigAnt executes the second set of “map” and “reduce” functions as follows:

- **Map:** $\langle \text{ID of transaction } t_j \in P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \text{valid } \{x\}, \{x\}\text{-projected database} \rangle$, and

- **Reduce:** $\langle \text{valid } \{x\}, \{x\}\text{-projected database} \rangle \mapsto \text{list of } \langle \text{valid frequent itemset } X, \text{expSup}(X) \rangle$.

Note that BigAnt pushes the user-specified anti-monotonic constraints into the big data mining process so that it directly discovers frequent patterns that satisfy the constraints.

To a further extent, Jiang et al. (2014) proposed the BigSAM algorithm to explore additional property of some anti-monotonic constraints. Specifically, BigSAM explores the succinctness of the constraints, which reveals that all and only those itemsets satisfying the succinct anti-monotonic (SAM) constraints can be explicitly and precisely generated using only individual items that satisfy the SAM constraints. For instance, any collection Y of geographic records with $\min(Y.GPSCoordinate) = 45^\circ\text{N}$ must consist of only records with GPS coordinate of 45°N . Hence, the BigSAM only needs to perform constraint checking in the first—but not the second—map function.

FUTURE RESEARCH DIRECTIONS

Due to the popularity of Web-based communities and social networking sites, high volumes of social media big data are available. For instance, as of March 2016, there were:

- 1.65 billion monthly active Facebook users, and 1.51 billion mobile monthly active Facebook users;
- 310 million monthly active Twitter users, and 1 billion unique visits monthly to Twitter with embedded tweets; and
- More than 433 million registered LinkedIn members worldwide, out of which more than 12 million registered Canadian members.

Embedded in these big data are rich sets of meaningful knowledge about the social networks. Hence, a logical future research direction is to

apply *social media mining and social network analysis* (Leung, Medina, & Tanbeer, 2013; Xu & Li, 2013; Jiang & Leung, 2014; Jiang, Kawagoe, & Leung, 2015; Leung et al., 2016) to social media data for discovery of rich sets of meaningful knowledge from these big data.

Many existing big data mining algorithms return the mined results in a textual form—e.g., a *textual list* of all (constrained or unconstrained) frequent patterns. As “a picture is worth a thousand words”, visual representation of the mining results is usually easier to comprehend for users than its equivalent textual representation. Thus, it is desirable to show the mining results interactively by applying the concepts of visual analytics. As such, to enhance user experience in exploring big data, the second future research direction is to incorporate *visual analytics and interactive technologies* (Zhang, Segall, & Cao, 2011; Leung, Carmichael, Johnstone, & Yuen, 2013) into big data mining so that the (constrained or unconstrained) frequent patterns mined from Big data are returned to the users in visual forms.

CONCLUSION

Big data analysis and mining aims to discover implicit, previously unknown, and potentially useful information and knowledge from big databases that contain high volumes of valuable veracious data collected or generated at a high velocity from a wide variety of data sources. Among different big data mining tasks, this chapter focuses on *big data analysis and mining for frequent patterns*. By relying on the MapReduce programming model, researchers only need to specify the “map” and “reduce” functions to discover frequent patterns from:

1. Big databases of precise data in a breadth-first manner (e.g., by using the SPC, FPC, and DPC algorithms) or in a depth-first manner (e.g., by using the PFP algorithm), and/or

2. Big databases of uncertain data (e.g., by using the MR-growth algorithm).

Such a big data analysis and mining process can be sped up (e.g., by using the BigAnt and BigSAM algorithms, which focus the mining according to the user-specified constraints that express the user interests). The resulting (constrained or unconstrained) frequent patterns mined from big databases provide users with new insights and a sound understanding of users’ patterns. Such knowledge is useful in many real-life information science and technology applications.

KEY TERMS AND DEFINITIONS

Anti-Monotonic Constraint: A constraint C such that, if an itemset S satisfying C , then any subset of S also satisfies C .

Big Data: High-velocity, high-value, and/or high-variety data with volumes beyond the ability of commonly-used software to capture, manage, and process within a tolerable elapsed time. These Big data necessitate new forms of processing to deliver high veracity (& low vulnerability) and to enable enhanced decision making, insight, knowledge discovery, and process optimization.

Data Mining: Non-trivial extraction of implicit, previously unknown and potentially useful information from data.

Frequent Pattern (Or Frequent Itemset): An itemset or a pattern with its actual support

(or expected support) exceeds or equals the user-specified minimum support threshold.

Frequent Pattern Mining: A search and analysis of high volumes of valuable data for implicit, previously unknown, and potentially useful patterns consisting of frequently co-occurring events or objects. It helps discover frequently co-located trade fairs and frequently purchased bundles of merchandise items.

Itemset: A set of items.

MapReduce: A high-level programming model, which uses the “map” and “reduce” functions, for processing high volumes of data.

Succinct Constraint: A constraint C such that all itemsets satisfying C can be expressed in terms of powersets of a fixed number of succinct sets using the set union and/or set difference operators. A succinct set is an itemset, in which items are selected from the domain using the usual SQL selection operator. In simple terms, a constraint C is succinct meaning that all and only those itemsets satisfying C can be explicitly and precisely generated using some precise “formula”.

Big Data Analytics for Tourism Destinations

B**Wolfram Höpken***University of Applied Sciences Ravensburg-Weingarten, Germany***Matthias Fuchs***Mid-Sweden University, Sweden***Maria Lexhagen***Mid-Sweden University, Sweden*

INTRODUCTION

Although information and communication technologies (ICT) were an important issue for Travel & Tourism (T&T) since the 1960ies (i.e. computer reservations systems, global distribution systems; Werthner & Klein, 1999), the difference today is that ICT has become a strategic issue for every tourism business (Buhalis, 2006). The special benefit tourism gains from ICT can be put down to the characteristics of the tourism product, being a service bundle ideally portrayed by electronic media and being jointly delivered by (usually) small-sized enterprises. Indeed, T&T is a highly information intensive sector, and not surprisingly, T&T represents the largest branch within the e-Commerce sector. In 2012, 45% of the EU online sales volume has been generated by the T&T sector, whereat in 2008 this figure stood only at 25%. Moreover, in the US already 51.5% of the total travel revenue is generated online (E-Marketer, 2012). However, although tourism shows high penetration rates with respect to web-based marketing & distribution, shortcomings become evident with respect to e-business networks (supply-chains) and integrated process automation (e-procurement, enterprise resource planning, etc.). Finally, significant adoption gaps are ascertained for ICTs in tourism SMEs to support market research, product development and strategic decision making (e-Business Watch, 2006).

The attractiveness of tourism destinations particularly depends on how communication and information needs of tourism stakeholders can be satisfied through ICT-based infrastructures so that sustainable knowledge sources can emerge (Buhalis, 2006). Although huge amounts of customer-based data are widespread in tourism destinations (e.g. web-servers store tourists' website navigation, databases save transaction and survey data, respectively), these valuable knowledge sources typically remain unused (Pyo, 2005). However, managerial effectiveness and organisational learning could be significantly enhanced by applying methods of *business intelligence* (BI) and *big data analytics* (Wong et al., 2006; Shaw & Williams 2009), offering reliable, up-to-date and strategically relevant information, such as tourists' travel motives and service expectations, information needs, channel use and related conversion rates, occupancy trends, quality of service experience and added value per guest segment (Min et al., 2002; Pyo et al., 2002). This makes clear why ICT and methods of BI are playing a crucial role in effectuating a *knowledge destination* by enhancing large-scale intra and inter-firm knowledge exchange. Indeed, the major challenge of knowledge management for tourism destinations is to make individual knowledge about customers, products, processes, competitors or business partners available and meaningful to others.

DOI: 10.4018/978-1-5225-2255-3.ch031

The objective of this chapter is to address the above deficiencies in tourism by presenting the concept of the tourism knowledge destination – a specific knowledge management architecture that supports value creation through enhanced supplier interaction and decision making. Information from heterogeneous data sources categorized into explicit feedback (e.g. tourist surveys, user ratings) and implicit information traces (navigation, transaction and tracking data) is extracted by applying semantic mapping, wrappers or text mining (Lau et al., 2005). Extracted data are stored in a central data warehouse enabling a destination-wide and all-stakeholder-encompassing data analysis approach. By using machine learning techniques interesting patterns are detected and knowledge is generated in the form of validated models (e.g. decision trees, neural networks, association rules, clustering models). These models, together with the underlying data (in the case of exploratory data analysis) are interactively visualized and made accessible to destination stakeholders. The technical architecture and implementation issues are discussed based on a prototypical implementation for the leading Swedish tourism destination, Åre (Höpken et al., 2015).

BACKGROUND

Since the widespread adoption of computerized reservation and booking systems in the 1980ies, comprehensive databases are available for all types of tourism transactions, i.e. the complete booking and consumption behavior (e.g. Passenger Name Record (PNR) databases of global distribution systems (GDS) or the airline on-time performance database of the Bureau of Transportation Statistics; BTS, 2012). Immediately, especially airline companies started to analyze such data as input to process and product optimization. A first prominent example in the area of revenue and yield management is the DINAMO system, introduced by American Airlines in 1988 (Smith et al., 1992). Further early examples can be found

for demand forecasting (Hueglin & Vannotti, 2001), prediction of cancellation or no-show behavior (Subramanian et al., 1999), or customer segmentation (Min et al., 2002).

Only very recently, data mining (DM) became increasingly important for tourism branches, due to its ability to discover previously unknown patterns in huge databases through explorative techniques and - compared to most statistical methods - to also identify non-linear relationships (Fuchs & Höpken, 2009; Fuchs et al., 2010; Höpken et al., 2011). Although, the potential of DM is not fully used in tourism yet, all major DM techniques are principally applied. More precisely, descriptive data analysis is widely used in form of reports or online analytical processing (OLAP) to visualize tourism arrivals depending on dimensions, like time/season, travel type or customer origin (TourMIS; Wöber, 1998; Destinometer; Fuchs & Weiermair, 2004). Methods of supervised learning, like classification, estimation and prediction are used to explain tourists' booking/cancellation or consumption behavior (Morales & Wang, 2008) and to predict tourism demand (Vlahogianni & Karlaftis, 2010). As a method of unsupervised learning, clustering is one of the most heavily used DM techniques in tourism, mostly applied to the task of customer segmentation as input to product differentiation, dynamic pricing or customer relationship management (Xia et al., 2010; Kuo et al., 2012).

With the uptake of the World Wide Web and its tremendous adoption in tourism, the topic of web DM gained more and more attention. *Web content mining*, i.e. the analysis of content from online platforms and websites, first of all deals with the analysis of user generated content (UGC), i.e. tourists' feedback and comments in blogs or review platforms, which currently constitute one of the most intensively researched topics in tourism (Bronner & Hoog, 2011). Methods of text mining are applied to the tasks of feedback aggregation and opinion mining or sentiment detection, typically based on statistical or linguistic approaches (Gräbner et al., 2012; Schmunk et al., 2014).

Additionally, web content mining increasingly deals with the extraction of knowledge about tourism markets and offers (market and concurrence analysis) (Walchhofer et al., 2010). Finally, *web usage mining* is dealing with the analysis of tourists' behavior when using online platforms or websites. Although current applications typically focus on descriptive analyses, like number of clicks or sessions depending on dimensions, like time, origin of user or URL, also supervised and unsupervised learning techniques have been applied, like customer segmentation for website adaptation and product recommendation (Wallace et al., 2004; Pitman et al., 2010) or (sequential) association rule mining for click-stream analysis (Jiang & Gruenwald, 2006).

THE KNOWLEDGE DESTINATION ARCHITECTURE

Although methods of BI and DM are partly used in tourism, their full potential, based on the huge amount of available data, is not yet utilized by far. Particularly, on the level of entire destinations, a comprehensive approach, i.e. a systematic integration of all data available from different stakeholder-based sources as well as a stakeholder-encompassing analysis approach, is missing.

The knowledge destination architecture fills this gap and distinguishes between a *knowledge generation* and a *knowledge application layer* (Figure 1; Höpken et al., 2011). The *knowledge generation layer* extracts destination-specific knowledge from structured and unstructured data sources, explicitly or implicitly generated by tourists (customer-based knowledge generation) or other destination stakeholders (supplier-based knowledge generation). For instance, content is generated by tourists through feedback mechanisms providing sources of standardized (e.g. surveys, evaluation platforms) and non-standardized data (e.g. blogs, review-platforms, etc.). Implicit knowledge can be made explicit by visualizing tourists' *information traces* (web-search, naviga-

tion behavior) through online application tracking and web-mining (Liu, 2008). Moreover, knowledge about tourists' buying behavior can be generated through mining transaction (booking) data. Finally, tourists' *mobility* behavior may be traced by GPS/WLAN-based position tracking (Zanker et al., 2009). Additionally, destination stakeholders generate knowledge about customers, products, processes, competitors and cooperation partners, extractable from existing data sources or websites, e.g. in the form of destination profiles, or availability or capacity information (supplier-based knowledge generation in Figure 1; Pyo, 2005).

The *knowledge application* layer provides knowledge-based services for customers as well as destination suppliers and stakeholders. *Customer-oriented knowledge application* comprises recommendation services or community services typically used to learn from prior consumption experiences of other customers (Xiang & Gretzel, 2010). Within the *supplier-oriented knowledge application* explorative data analyses (EDA), OLAP as well as DM (predictive analytics, classification, clustering and association rules) allow the de-centralized management and access of competitive knowledge by the destination management organization (DMO) as well as private and public destination suppliers. Crucial management functions that support organizational learning and strategic decision making with a concern to product innovation and destination development are provided, such as benchmarking, business performance management, forecasting, multi-channel management, dynamic pricing and online community management (blog aggregator, alert functions, etc.) (Pyo et al., 2002).

The Tourism Data Warehouse Model

Core of the knowledge destination architecture and the prerequisite for destination-wide, stakeholder-encompassing analyses is a central *data warehouse* (Cho & Leung, 2002). Beside organizational constraints and privacy concerns, this first development step often fails due to the

Figure 1. The knowledge destination

heterogeneity of available data and the absence of a homogeneous data model. Although data modeling approaches and design patterns for business areas, like retail/sales, procurement, accounting, human resources, E-commerce, etc., already exist, there is no overall and general data warehouse model available for the tourism domain in general and for tourism destinations in specific (Kasavana & Knutson, 1999). Thus, agreeing on a common understanding of relevant business indicators, its underlying business processes and their characteristics and defining an appropriate and expressive destination data warehouse model is a crucial step towards powerful decision support

in a knowledge destination. The first activity of defining a destination data warehouse model is to identify most relevant business indicators which fulfill the requirements for a powerful decision support. Based on a literature review (Pyo et al., 2002; Cho & Leung, 2002; Pyo, 2005; Wang & Russo, 2007) and input from stakeholders of the Swedish tourism destination, Åre, relevant business indicators are defined and summarized in Table 1.

Generally, two concurrent approaches exist for developing a data warehouse model: while the *dimensional modeling* approach (Kimball, 2008) offers the advantage of a simple, straight-forward

Table 1. Business indicators

1 Economic performance	bookings, overnights, prices, occupancy, sales
2 Customer behavior	2A <i>Website navigation & search</i> : referrer sites, sessions, page views, search terms 2B <i>Booking and consumption behavior</i> : booking channels, conversion rates, days to arrival, length of stay, cancellations, guest tracking 2C <i>Customer profile</i> : country of origin, age, gender, skiing travel behavior, customer life time value, average/last length of stay, preferred type of accommodation, preferred mode of accommodation booking, preferred mode of transportation, purpose of visit
3 Customer perception and experience	3A <i>Destination brand awareness</i> : destination brand visibility, destination knowledge, information sources 3B <i>Destination value areas (functional & emotional)</i> : skiing & non-skiing winter activities, summer activities and attractions, services and features, atmosphere, social interaction 3C <i>Value for money and customer satisfaction</i> : functional value, emotional value, satisfaction 3D <i>Loyalty</i> : cognitive / affective loyalty, conative loyalty

Table 2. The tourism data warehouse bus matrix

Business Process	Indicators	Fact Table Type	Dimensions														
			Connectivity	Marketing	Survey	Referral	Session	Event	URI	Var Feedback	Feedback	Location	Channel	Supplier	Vendor	Product	Customer Demographic Profile
Booking	1, 2B, 2C	AS							x								
Stay	1, 2B, 2C	T										x					
Consumption	1, 2B, 2C	T										x		x		x	
Location Tracking	2B	T										x					
Info Request	2A	T											x			x	
Web Navigation	2A	T							x					x		x	
Feedback	3A-D	T							x		x	x	x	x	x	x	
Capacity	I	PS															
Marketing Activity	I	T															

database design, supporting powerful analyses and a relatively good understandability by end users, the *fully normalized modeling* approach (Inmon, 2002) offers the advantage of a relatively better support of data integration, as redundancies are avoided and the identification of inconsistencies is simplified (especially if inconsistencies should be solved in underlying operational databases as well). In case of a tourism destination, the focus is not that much on reducing inconsistencies (i.e. especially not across different operational systems, due to the relative independence of stakeholders compared to departments of a single company), but rather on enabling powerful analyses on data of the whole destination. Thus, the approach of dimensional modeling seems most appropriate for defining a tourism destination data warehouse model. Table 2 provides an overview of the destination data warehouse model (bus matrix), listing identified business processes, necessary to support the defined indicators, the type of the corresponding fact table (transaction (T) = one entry per transaction, periodic snapshot (PS) = one entry per each period in time, accumulated snapshot (AS) = one entry covering all phases of a process) and, finally, all dimensions linked to a process (Kimball, 2008). Following the fundamental concept of *conformed dimensions*, most dimensions in a tourism data warehouse are used by several processes and, thus, such processes share the same physical dimension tables in the data warehouse. Conformed dimensions interlink the corresponding processes and enable cross-process analyses, for instance identifying relationships between customers' booking/consumption, web navigation and feedback behavior, respectively.

Technical Architecture and Implementation Issues

Figure 2 sketches the overall architecture of the knowledge destination. The *knowledge generation layer* comprises structured and unstructured data sources, the process of extracting relevant data, transforming source data into a homogeneous data

Figure 2. Knowledge destination framework architecture

Source: Höpken et al., 2011, p. 420

format appropriate for further analyses and storing/loading the data into the data warehouse (ETL), the data warehouse as central and homogeneous destination data store and, finally, DM and knowledge generation. The *knowledge application layer* comprises a destination management information system (DMIS) as central application offering data visualization and DM functionalities to destination stakeholders and managers.

Data Extraction (ETL)

Extraction, transformation and loading represents the process of extracting data from different data sources (e.g. operational databases, CRM systems, web-server log-files, etc.), transforming data into a format appropriate for visualization or DM activities and loading or storing data into a database (typically a data warehouse). The most important requirement related to *data extraction* in the context of tourism destinations is the support of all possible data sources and data formats, including structured data, like text files, databases or application-specific formats (e.g. SPSS files, excel files, etc.) or unstructured data, like html files or free text (typically converted into structured data by means of wrappers and text mining).

With regard to *data transformation*, in the context of the knowledge destination, data migration is most critical, i.e. value domain transformations, combination/separation of data elements and structure mapping, and record linkage (identification of duplicate entries, e.g. customers from different source systems, due to the heterogeneity and independence of operational systems of different destination stakeholders). Additionally, a powerful ETL process has to support different execution chronologies (e.g. periodically, on-demand or event-driven) and different incremental update strategies. In the course of the prototypical implementation of the knowledge destination for the Swedish destination Åre, RapidMiner and the Rapid Analytics BI server have been chosen, due to its full range of support of all components of the knowledge destination architecture, especially DM activities.

Data Warehouse

The knowledge destination data warehouse builds on a multi-dimensional data modeling (MDM) approach (Kimball et al., 2008; Höpken et al., 2013). In the course of the prototypical implementation of the knowledge destination, the Dimensional

Fact Model (DFM) has been chosen as graphical modeling notation, due to its good understandability (Golfarelli & Rizzi, 1998). Moreover, simple spreadsheets have been used to define the detailed dimensional model, due to insufficient tool support for DFM. Nevertheless, UML extensions and CWM (Common Warehouse Metamodel) are reasonable alternatives.

Data Mining

Due to the need of expert supervision and often long execution time for certain DM processes, not all processes can be executed by end users autonomously. Thus, DM processes are either executed online, triggered by the end user within the DMIS, or offline, i.e. triggered by data changes caused by corresponding ETL processes. Several open source tools for DM currently exist. For instance, RapidMiner is a powerful DM tool and together with the rapid analytics BI server offers a full-functional framework for executing DM processes in a client-server environment. More precisely, RapidMiner includes all WEKA DM methods and due to its support of web DM, text mining and time series analysis it seems most appropriate for implementing the knowledge destination architecture. However, an important limiting factor of DM tools in general and RapidMiner in specific is the performance concerning execution time and main memory consumption. Depending on available hardware, this especially limits the number of DM processes, which can be executed online.

DMIS

The Destination Management Information System (DMIS) represents the interface of the knowledge destination architecture to the end user. DMIS enables to access the data and knowledge stored in the central data warehouse and to execute data analyses as a mean of decision support. Available functions and analyses can be differentiated into reporting, i.e. offering predefined reports, OLAP

and DM. Specific frameworks for developing MIS or cockpit solutions, e.g. RapidMiner Enterprise Edition (www.rapid-i.com) or Pentaho BI, have been analyzed and compared with developing a specific web application from scratch. Integrating specific functionalities, especially in the area of adaptive decision support based on meta-learning, is an important requirement in the context of the knowledge destination architecture in order to reach a high level of usability and understandability. Thus, the prototypical implementation for the destination of Åre makes use of a self-developed web application, based on the Ruby on Rails open-source web development framework (rubyonrails.org).

Decision Support by Interactive Visualization and Data Mining

Supporting destination and stakeholder management decision making takes place by explorative data analysis (EDA) and OLAP on the one hand and more complex DM techniques on the other hand. Exemplarily for EDA, OLAP and DM, a description of the framework for UGC extraction and analysis, which is integrated in DMIS-Åre, will follow next.

Online reviews regarding the Swedish destination Åre are gained from social media platforms *TripAdvisor.com* and *Booking.com* and text-processing techniques are applied to automatically extract single statements from each of the reviews. Subsequently, by using machine-learning techniques and a dictionary-based approach, these statements are classified as either 'positive' experiences, 'negative' experiences or 'neutral' (Liu, 2011). Moreover, statements are classified into product areas, like 'FoodBreakfast', 'Rooms', and 'Service-Personnel'. From the proportion of classified positive and classified negative statements, an average feedback value (normalized between 0-1) is computed. By following Hippner and Rentzmann (2006), the framework for UGC extraction and analysis comprises five steps (Schmunk et al., 2014):

1. **Document Selection:** Relevant review sites are identified as input to the mining process for the sentiment analysis regarding hotels in the destination Åre. The review sites *Booking.com* (10 hotels and 248 reviews) and *TripAdvisor.com* (17 hotels and 1,193 reviews) were selected. To collect relevant pages from review sites, a web crawler was used, fetching html pages and following contained links based on regular expressions specified for each site (ibid, 2014, p. 256).
2. **Document (Pre-)Processing:** The pre-processing of collected html documents includes four steps: a) extraction of relevant opinion texts from html-code based on regular expressions, b) removal of empty reviews, c) filtering of English texts, since sentiment analysis is language dependent (e.g. wordlists in the case of the dictionary-based approach or stop word removal and stemming in the case of machine-learning approaches),¹ and d) generation of single statements based on sentence end characters as delimiters (Schmunk et al., 2014, p. 257). Pre-processing of *TripAdvisor.com* delivers 127 reviews and 1,296 usable single statements, while from *Booking.com* 81 reviews and 220 statements are gained (total no. of reviews = 208; total no. of usable statements = 1,516).
3. **Mining:** Mining includes the sub-tasks recognition of properties, subjectivity, and sentiment, respectively. For machine learning methods training data were created for all classification tasks (property, subjectivity and sentiment). Sentences are tokenized, stop words removed, words reduced to their stem, and finally, a word vector is created based on TF-IDF scores. Subsequently, the machine learning methods Naïve Bayes, Support Vector Machines (SVM) and k-nearest neighbor (k-NN) are applied. For the dictionary-based approach, a word list for each class (property, subjectivity and sentiment) is employed. In this case, the class of a sentence is directly deduced by the wordlist to which the majority of contained words belong to (ibid., 2014, p. 258).
4. **Evaluation:** A 10-fold cross-validation is used to evaluate the machine-learning models, while the dictionary-based approach is evaluated by comparing the results with pre-classified test data. For the recognition of properties SVM gained the highest accuracy (i.e. percentage of correctly classified statements within test data) of 72.35%. The highest accuracy of 82.63% for subjectivity recognition was achieved by the dictionary-based method. The best result for sentiment recognition is gained again by the SVM method, showing an accuracy of 76.80% (ibid, 2014, p. 260).
5. **Usage:** The outcome of the sentiment analysis provides valuable information on customer reviews and opinions in a structured format (ibid, 2014, p. 262). Thus, data extracted from the review sites (e.g. review date, hotel name, demographic data of reviewer, and the review text itself) is enriched by the product properties that the opinion is linked to and its orientation (sentiment) and finally stored in the multi-dimensional destination data warehouse of DMIS-Åre (Höpken et al., 2013). Thus, social media knowledge is made available for powerful OLAP analyses as discussed below.

The DMIS-Åre dashboard in Figure 3 displays the customers' (i.e. guest) profile directly deduced from social media content, such as travel purpose, travel companions, number of UGC-based statements by origin countries, etc.

The dashboard in Figure 4 displays the 'average feedback' value extracted and calculated from UGC as described above, grouped by hotel 'product areas' and major hotels in Åre. Hotel and destination managers can, thus, monitor the performance in terms of customer feedback (UGC) in total, or grouped by hotel product area. Moreover, UGC-based performance metrics can

Figure 3. DMIS-Åre dashboard: guest profile extracted from social media sites

be benchmarked among various accommodation suppliers (Fuchs & Weiermair, 2004).

As outlined in the section about the *Tourism Data Warehouse Model*, a final powerful feature is to join so far disconnected and separately filed knowledge areas through common (conformed) dimensions across different business processes (Höpken et al., 2013). This condition, namely to relate customer feedback to web-navigation and booking behavior is considered as crucial for enhanced organizational learning and creativity processes in destinations (Fuchs et al., 2014, p. 201). More concretely, this procedure provides analyses across the three prototypically implemented processes *Web Navigation* (site clicks, sessions), *Booking* (total bookings, booking price, number of persons/booking, average time between booking and arrival, average stay duration/booking) and *Feedback* (total feedback answers, average feedback value) (Höpken et al., 2015). As mentioned, the average feedback value is generated not only through UGC extracted from various social media platforms. Rather, the multi-dimensional structures of the data warehouse are populated also by feedback data from destination brand equity surveys (Chekalina et al. 2014), real-time feedback from guests during their stay provided by an electronic customer registration and survey tool (e-CRST) accessible via Quick-Response codes (Höpken et al., 2012), and, finally, data from customer surveys conducted by various destination accommodation suppliers.

Thus, the following cross-process analyses link customer feedback from different sources with data from the web-navigation and booking process, respectively. For instance, for each country of customer origin, Figure 5 lists key performance indicators (KPIs) across the booking process, the web navigation process and the feedback process (Schmunk et al., 2014, p. 262). For instance, and interestingly enough, the cross-process analysis reveals that Finnish tourists show a relatively high

Figure 4. DMIS-Åre dashboard: UGC-based feedback value grouped by Åre hotels and product area

average feedback value (0.812), pay a relatively high average booking-price per overnight (7,852 SEK) and are characterized by a relatively long average duration of stay (6.16 days). In contrast, tourists from Belgium show a relatively low average feedback value (0.702), pay a comparatively lower booking-price per overnight (5,355 SEK), and show a relatively short average duration of stay (5.36 days).

FUTURE RESEARCH DIRECTIONS

Integration of Data Mining and OLAP

Visualizations of DM models, such as decision trees, regression models or cluster models, are complex and typically displayed by DM tools in a form which is usually difficult to understand for managers. Thus, such models are vanished manually and presented through static reports with no direct integration of OLAP functionalities. Thus,

managers get no hints for DM models relevant in the context of a specific OLAP analysis, and DM models are not related to other information available within the data warehouse. However, to overcome these limitations, DM models have to be integrated directly into the dimensional structures of the data warehouse and existing OLAP functionalities can be used for their interactive visualization and relating to other information. Cluster models, for example, can be stored in the data warehouse by a specific cluster dimension linked to the corresponding fact table, if the clustering is based on several dimensions, or by a cluster membership attribute within a dimension, if the clustering is based solely on one dimension (e.g. customer segmentation). Moreover, association rules can be stored as a new fact table, but reusing existing dimensions, like product or customer. Thus, future research has to analyze how DM models can be optimally integrated into the data warehouse in order to enable a powerful integration of DM and OLAP analyses (Mayer et al., 2015).

Meta Learning and Adaptive MIS

Typically, managers are overwhelmed with the question, which DM method is best suited for the analysis at hand. Additionally, in most situations

an optimal result cannot be reached in one single step, but rather an iterative and interactive process is needed, what, in turn, typically requires guidance based on domain-specific experience. Such guidance in selecting appropriate DM methods and parameters or the best approach for improving and refining DM results, can be provided to managers through concepts of meta-learning. Following the approach of an adaptive recommender system, the system adapts available choices or even the overall user dialog and offers recommendations for DM methods, parameters or optimization steps (Ricci et al., 2011). An interesting future research questions is, how existing approaches from meta-learning and recommender systems can be combined and applied to the concrete context of an adaptive MIS within a tourism knowledge destination.

CONCLUSION

This chapter presented a BI architecture to apply DM techniques to the tourism domain and more concrete to tourism destinations. The proposed *knowledge destination architecture* supports knowledge creation and enhanced decision making in tourism destinations. As core component of the knowledge destination, a multi-dimensional

data warehouse model has been presented which considers all business processes and corresponding dimensions most relevant to any tourism destination, and, thus, serves as reference model for similar implementations in a tourism destination context. Subsequently, UGC-based analyses from the area of OLAP and DM have been presented. Moreover, crucial technical aspects of the BI architecture related to the area of data extraction (ETL), data warehousing, DM and a destination management information system (DMIS) as user interface have been critically discussed and concepts and techniques suitable to the tourism knowledge destination have been presented. Finally, veins of future research have been sketched. The concept of the tourism knowledge destination has been prototypically implemented and validated within the leading Swedish tourism destination Åre. Not only has the concept proven to be viable but also the strategic importance of this system for destination stakeholders was proved through a remarkable high final user acceptance. Especially the flexible integration of customer feedback in form of survey results into the data warehouse and DMIS appeared to be a powerful and promising approach to knowledge creation in the tourism domain.

KEY TERMS AND DEFINITION

Adaptive Management Information System:

A management information system adapting its user interface and interaction strategy depending on user preferences and past user behavior and satisfaction.

Computer Reservation Systems (CRS) / Global Distribution Systems (GDS): Computer systems providing information like prices and availabilities for a wide range of tourism products (e.g. hotels, flights, car-rental, etc.) and supporting the full booking, settlement and after-sales processes.

Customer-Based Data: Data provided by customers either intentionally, like demographic data, reviews and comments, or data provided unintentionally, like data on web-navigation, booking or consumption behavior.

Data Warehouse Bus Matrix: Visualization of business processes, corresponding facts and dimensions for a multi-dimensional data warehouse model.

Destination Management Information System (DMIS): A management information system specifically designed to enable improved decision support for the destination management organization and other stakeholders of a tourism destination.

Destination Management Organization (DMO): Organization which coordinates the many constituent elements of the tourism prod-

uct; provides visitor services and the necessary information structure to market the destination in a most democratic way to enhance residents' well-being.

Multi-Dimensional Data Modeling (MDM):

A modeling paradigm for data warehouse models building on a separation of measurements, called facts, and surrounded context, called dimensions.

Tourism Destination: Agglomeration of companies and organizations involved in producing and marketing the overall tourism product within a geographical area; strategic unit providing all necessary resources whose integrated activities allow tourists with the kind of experiences they expect.

Tourism Knowledge Destination: Novel concept of a tourism destination that supports knowledge creation, transfer and enhanced decision making among destination stakeholders by applying techniques from business intelligence and data mining.

Tourist Feedback: Feedback on tourism products, suppliers or whole destinations, provided by tourists in structured and unstructured ways, e.g. in the form of customer ratings, comments or product reviews.

Big Data Time Series Stream Data Segmentation Methods

Dima Alberg

Shamoon College of Engineering (SCE), Israel

INTRODUCTION

Big data time series data streams are ubiquitous in finance, meteorology and engineering. It may be impossible to process an entire “big data” continuous data stream or to scan through it multiple times due to its tremendous volume. In Heraclitus’s well-known saying, “*you never step in the same stream twice*,” and so it is with “big data” temporal data streams.

Unlike traditional data sets, big data continuous data streams flow into a computer system continuously, in a non-stationary way and with varying update rates. They are time-stamped, fast-changing, massive, and potentially infinite.

Under these circumstances, they represent an application area of growing importance in the data mining research. For example, sensors generate one million samples every minute therefore the primary purpose of time series data stream segmentation is dimensionality reduction. This technique is used in many areas of data stream mining as: frequent patterns finding, structural changes and concept drifts detection (Tabassum & Gama, 2016), time series classification and prediction (Hulten & Domingos, 2003), time series similarities searching (Mori, Mendiburu, Keogh & Lozano, 2016) etc. The main principle of segmentation algorithms concludes in reducing the big data time series dimensionality by dividing the time axis into intervals behaving approximately according to a simple model. A good big data time series data stream segmentation algorithm must be OFASC (Online, Fast, Accurate, Simple and Comparable). For example the Sliding Window algorithm (Keogh, Chu, Hart, & Pazzani, 2004) on

the one hand is online (O), very fast (F) and relatively simple (S) for using in online segmentation applications but on the other hand, it sometimes gives poor accuracy (A) and does not allow to perform online multivariate segmentation (C). Therefore, we will classify this algorithm to OFS segmentation algorithms domain.

The segmentation problem can be defined in following way: first, given a time series data stream to produce the best representation such that the maximum error for any segment does not exceed some user specified confidence level error threshold. It is important to add, that using a relative parameter such as confidence level will allow to evaluate an online multivariate segmentation and second, to construct a user friendly segmentation application which will evaluate and compare the proposed online segmentation algorithms in real time. As we shall see in later sections, the state-of-the-art segmentation algorithms do not meet all these requirements.

The rest of the paper is organized as follows. In Section 2, we provide a literature review of three state-of-the-art online piecewise linear segmentation algorithms. In Section 3, we provide a methodology for improving the existing state-of-the-art online segmentation algorithms. The proposed methodology based on novel bound error estimation, which uses a relative probability parameter instead of maximum error nominal parameter and meets the proposed OFASC requirements. Section 4 briefly demonstrates a real-time segmentation application. Finally, in Section 5 and 6 we provide brief and meaningful empirical comparison of the proposed algorithms and suggest final conclusions.

DOI: 10.4018/978-1-5225-2255-3.ch032

BACKGROUND

Several high level representations of time series have been proposed in the research literature, including Fourier Transforms (Keogh et al., 2000), Wavelets (Chan & Fu, 1999), Symbolic Mappings (Das, Lin, Mannila, Renganathan, & Smyth, 1998; Perng et al., 2000) and Piecewise Linear Approximation or PLA: (Chan & Fu, 1999; Ge & Smyth, 1999; Hunter & McIntosh, 1998; Junker, Amft, Lukowicz, & Tröster, 2008; Keogh et al., 2004; Lavrenko, Schmill, Lawrie, Ogilvie, Jensen, & Allan, 2000; Li, Yu, & Castelli, 1998; Osaki, Shimada, & Uehara, 1999; Park, Lee, & Chu, 1999; Qu, Wang, & Wang, 1998; Shatkay & Zdonik, 1996; Vullings, Verhaegen, & Verbruggen, 1997; Wang & Wang, 2000).

In this work, our attention will confine to PLA, perhaps the most frequently used representation in continuous time series data streams. Obviously, all piecewise linear segmentation algorithms can also be classified as batch or online (Vullings et al., 1997). The problem discussed by (Keogh et al., 2004) is actually how to build online, fast and accurate algorithm for piecewise linear segmentation of time series data stream, because on the one hand, the main problem of online Sliding Window algorithm (Keogh et al., 2004) concerns in its poor accuracy (Qu et al., 1998; Wang & Wang, 2000) and its inability to look ahead. On the other hand the offline accurate Bottom Up (Keogh et al., 2004) algorithm is impractical or may even be unfeasible in a data mining context, where the data are in the order of terabytes or arrive in continuous streams. This problem is very important because for scalability purposes the proposed piecewise linear segmentation algorithm needs to capture the online nature of sliding windows and yet retain the superiority of Bottom Up.

In 2004 Keogh et al. (Keogh et al., 2004) introduced online Sliding Window Bottom Up (SWAB) algorithm which scales linearly with the size of the dataset, requires only constant space, produces high quality approximations of the initial time series data, and can be seen as operating on

a continuum between the two extremes of Sliding Windows and Bottom-Up. The authors have shown that the most popular Sliding Window approach generally produces very poor results, and that while the second most popular approach, Top-Down, can produce reasonable results, it does not scale well with massive time series stream data.

MAIN FOCUS

As indicated in (Keogh et al., 2004), the main problem with the Sliding Windows algorithm is its inability to look ahead, lacking the global view of its offline (batch) counterparts. The Bottom-Up and the Top-Down (Junker et al., 2008; Keogh et al., 2004) approaches produce better results, but are offline and require the scanning of the entire data set. The SWAB algorithm has three nominal input parameters, which need to be defined carefully by the user in order to obtain an accurate segmentation model. For example, often the user obstructs to determine for the value of the maximal error threshold, because the data has very noisy non-stationary behavior. Therefore, in order to produce an accurate segmentation model, the user needs to perform the preprocessing of the obtained data or to perform a time consuming experiment design. Second, the inner loop of the SWAB algorithm simply invokes the Bottom-Up algorithm each time. This results in some computation redundancy and increases the computational complexity of algorithm. In this paper we introduce two new algorithms ISW (Interval Sliding Window) and ISWAB (Interval Sliding Window and Bottom Up) which decreases computational redundancy and complexity of SWAB (Sliding Window and Bottom Up) (Keogh et al., 2004) algorithm.

The performance of the Sliding Window and SWAB algorithms depends on the value of maximal error. As maximal error goes to zero the Sliding Window and SWAB algorithms have the same performance, since they would produce multiple short segments with no error. At the opposite end, as the maximal error becomes very

large, the algorithms once again will all have the same performance, since they will simply approximate a data stream with a single best-fit line. Keogh et al. (Keogh et al., 2004) recommend test the relative performance for some “reasonable value” of maximal error, a value that achieves a good tradeoff between compression and fidelity. Because this “reasonable value” is subjective and dependent on the data mining application and the data itself, they did the following. First, they chose a “reasonable value” of maximal error for each dataset and then bracketed it with 6 values separated by powers of two. The lowest of these values tends to produce an over-fragmented approximation, and the highest tends to produce a very coarse approximation. Second, they chose performance in the mid-range of the 6 values which by their opinion should be considered most important. Obviously, the maximal error calculation routine proposed by Keogh et al. (Keogh et al., 2004) is very subjective and requires multi pass computational efforts. In the proposed ISWAB algorithm it is possible to derive the maximal error by using Hoeffding bound and one pass calculation. In fact, a similar approach was used in the VFDT decision tree induction algorithm introduced in (Hulten & Domingos, 2003).

Suppose we have a segment A with range R_A and n_A observations and segment B with range R_B and n_B observations which belong to a sliding window S of time series T . Assume that $\bar{x}_A$ and $\bar{x}_B$ are the sample means of segments A and B respectively, then the new created segment AB will have range R_{AB} , $n_A + n_B$ observations and sample mean $\bar{x}_{AB}$. Finally, the Hoeffding bound states that the true mean of the merged segment AB lies with confidence level of $1 - \delta$ in the interval where

$$\epsilon = \sqrt{R_{AB}^2 \frac{\ln(1/\delta)}{2(n_A + n_B)}}. \quad (1)$$

According to Motwani and Raghavan (1998) the Hoeffding bound is independent of the distribution generating the examples. This bound is

applicable to all situations where observations are independent and generated by a stationary distribution. Important to note, that Hoeffding bound is additive, its error is absolute and it does not require calculation of expected means of two merged segments. It is easy to show, that when a confidence level $= 1$, the Hoeffding error value is equal to zero meaning that the observed and the segmented time series data streams are the same.

In case of Sliding Window algorithm the proposed technique ISW works in following manner. Each time a new observation arrives the algorithm calculates the Hoeffding bound using Equation 1 and a user defined confidence level, then in case the new calculated error is greater than the previously calculated Hoeffding bound, the algorithm starts a new sliding window, otherwise it continues with the current sliding window. This incremental technique on the one hand is more sensitive to data stream concept drift changes and on the other hand allows to create relatively large segments when the data stream is stable and therefore to decrease significantly the running time of the proposed algorithm. The pseudocode for the ISW algorithm is shown in the Table 1.

The following numerical example briefly explains main calculation procedure of the ISW algorithm. Suppose that the current sliding window segment includes four observations: 1, 2, 3 and 4 (Table 2). Now, a new, fifth observation arrives and the ISW algorithm checks whether to start a new segment or to continue updating the previous one. The current segment range equals to 0.8 (4.8-4.0), the number of observations is 4 and with the user specified confidence level of 95% the value of Hoeffding bound equals to 0.06. Now, with the aid of the new, fifth observation we will recalculate the linear interpolation model error. The new model error equals to 0.025. This error is lower to previously calculated Hoeffding bound (0.06), thus the algorithm will increase the current segment.

The main similarity of the SWAB and ISWAB algorithms consists in the pairwise linear bottom up segmentation approach. This approach assumes

Table 1. The ISW online algorithm

Input: Data stream, DS Confidence Level,
Output: ISW Segmented data stream.
<pre> anchor = 1; while not finished segmenting time series i = 2; *Bound and Error Calculation while Model_error < Hoeffding_Bound Model_Error(Segment[anchor: anchor + i]) Hoeffding_Bound(Segment[anchor],) i = i + 1; New_Segment = Create_Segment(T[anchor: anchor + (i-1)]) Segment = Merge(Segment, New_Segment) anchor = anchor + i; </pre>

Segment	1	1	1	1	2

creating the finest possible linear interpolation of the time series, so that $n/2$ segments are used to approximate the n -length time series. Differently from the SWAB algorithm the proposed ISWAB algorithm chooses between the best linear

interpolation and regression models. Finally, the pseudocode for the proposed ISWAB algorithm is shown in Table 3.

The following numerical example briefly explains main calculation procedure of our presented

Table 3. The ISWAB online algorithm

Input: Data stream, DS Confidence Level, Sliding Window size, SW
Output: ISWAB Segmented data stream.
<pre> Create the Sliding Window buffer of size SW For (i = 1, length(SW), 2) Segment = Concatenate(SW[i: i + 1]); *Bound and Error Calculation For (i = 1, length(Segments.Count) - 1) Bound(i) = Hoeffding_Bound(Segment[i], Segment[i+1],) Error(i) = Model_Error(Segment[i], Segment[i+1]) *Merging the Segments while (min(error(k)) < Bound(k)) index = min(error(k)); Segment(index) = Merge(Segment(index), Segment(index+1)) delete(Segment (index+1)) Error(index) = Model_Error (Segment[i], Segment[i+1]) Bound(index) = Hoeffding_Bound(Segment[i], Segment[i+1],) Error(index-1) = Model_Error (Segment[i-1], Segment[i]) Bound(index-1) = Hoeffding_Bound(Segment[i-1], Segment[i],) Shift the Sliding Window to the Right Remove the Left Segment from the Sliding Buffer </pre>

Table 4. Observations for ISWAB numerical example

n	1	2	3	4	5	6	7

Segment	1	1	2	2	↔ ₂	3	3

ISWAB approach. Suppose that a sliding window contains 3 segments with lengths of two, three, and two observations respectively. Table 4 shows the numerical values of seven collected observations.

The main question is which segments to merge: the first with the second or the second with the third? If we merge the first two segments then the number of observations in the merged segment equals to 5 and its range is 6.6, otherwise if we merge the second and the third segment we obtain the same number of observations and the range of 5.5. Supposing that our selected confidence level is 95%, we will calculate the Hoeffding bounds for the two proposed scenarios. For the first scenario according to the formula 1 we have Hoeffding bound value ε of 0.47 and for second the error value is 0.39. In the opposite case, the linear interpolation model error for the first scenario equals to 0.89 and it will be described by the following linear interpolation equation, whereas the second scenario's linear interpolation model has error of 0.078 and the following linear interpolation equation. Choosing the minimal model error value of 0.078 which is lower than the previously corresponded Hoeffding bound value 0.39 the ISWAB algorithm we will perform merging of segments 2 and 3.

The proposed techniques have the following advantages. First it is more convenient to define a confidence level as input rather than the maximum error threshold. Second our techniques allow to compare ISW and ISWAB algorithms across different time series and data streams mining domains, since they require relative confidence level parameter as input. Third the main advantage of the proposed algorithm is that it encourages merging of big segments. Suppose that we have 3 segments A , B and C with the same range but

with different lengths (measured by the number of examples), then it is easy to show that when $n_A + n_B > n_B + n_C$ the our proposed algorithm tends to merge bigger segments.

$$\epsilon_{A+B} = \sqrt{R_{AB}^2 \frac{\ln(1/\delta)}{2(n_A + n_B)}} < \sqrt{R_{BC}^2 \frac{\ln(1/\delta)}{2(n_B + n_C)}} = \epsilon_{B+C} \quad (2)$$

EXPERIMENTAL RESULTS

Our experimental study is aimed at estimating the accuracy and comparing the performance of the proposed algorithms. The first part was focused on stationary time series data streams (TSDS) and the second one was focused on non stationary data streams. The proposed algorithms were implemented using C# programming language and tested on a PC Intel Core2Duo at 3 GHz with 2GB RAM and 256 GB hard disk.

The stationary data streams were generated from two synthetically distributed normally distributed time series ND25 and ND100 whereas the non-stationary data streams were obtained from two Israel's daily financial indexes TA25 and TA100 (www.finance.yahoo.com). These finance indexes behavior strongly depends on time and therefore they demonstrate non stationary behavior. The few descriptive statistics for the four selected time series is shown in Table 5.

Parametrically, the ND25 time series is similar to TA25 because their averages, standard deviations and lengths are equal. Same thing is right

Table 5. Descriptive statistics

TSDS	N*	Max	Min	Avg.	St.Dev.
ND25	1,228	1,693.82	-29.21	748.06	244.32
ND100	1,228	1,426.14	-22.79	756.70	225.00
TA25	1,228	1,237.13	333.90	748.06	244.32
TA100	1,228	1,189.04	341.04	756.70	225.00

(*by N we denote the total number of observations with at least one minute interval commit frequency)

Figure 1. The ISW algorithm accuracy

regarding to TA100. Figure 1 demonstrates the ISW algorithm evaluation on the four collected time series. The blue columns point out the non-stationary data as financial indexes TA25 and TA100 and red stationary data e.g. similarly generated normally distributed processes ND25 and ND100. The most obvious result is that ISW produces more accurate results on stationary data (red columns) when the user specified confidence level is greater than 80%. In case of non-stationary data streams the ISW algorithm produces stable but less accurate results. This stable quality pattern results from the ISW algorithm ability to detect mean concept drifts in time series data stream behavior.

Figure 2 demonstrates the performance results of ISW algorithm. Actually, this figure Y axis shows the number of created segments when it is obvious that a large number of segments increases the evaluation time of algorithm and vice versa. As

previously mentioned the ISW algorithm produces good accuracy results for our collected stationary data. From Figure 2 we will conclude that when user specified confidence level greater than 80% the ISW and ISWAB algorithms produces similar quantity of segments (+300).

Now take our attention to ISWAB algorithm. On the one hand the ISWAB algorithm significantly outperforms the ISW algorithm and has good accuracy results for two sorts of collected data (Figure 3) when user specified confidence level is greater than 80%.

On the other hand, in case of non-stationary data the ISWAB algorithm creates large number of segments and this fact significantly increases the algorithm run time. In case of stationary data streams (red columns) the ISWAB algorithm creates small number of segments (from 40 to 50) and significantly outperforms the previously mentioned ISW algorithm.

Figure 2. The ISW algorithm performance

Figure 3. The ISWAB algorithm accuracy

FUTURE RESEARCH

Another promising direction for future research based on this work is the multi-sensor fusion area. One straightforward direction for further research in this case is to employ several sensors, thus extracting as much information as possible. In multi-sensor data fusion systems, these sensors can be used to measure the same quantities, which is especially helpful in case of sensor failure. Alternatively, different quantities associated with the same state of nature can be measured by different sensors. In all of these cases, observations are available from several sources and the information provided by each of the sources should be combined. We believe that the algorithms developed here can reduce uncer-

tainty and obtain a more complete knowledge in this area of research.

CONCLUSION

This study has highlighted a number of limitations in existing state-of-the-art online piecewise linear segmentation approaches: Sliding Window (SW) and SWAB. First, the new relative parameter of confidence level was used instead of nominal input parameter of maximal error threshold. This improvement has two advantages: first is that the user does not need to preprocess the original time series data stream in order to detect reasonable maximum error value and second is that the proposed technique allows to perform cross

comparisons between different time series data streams. Second, the implementation of new real time application was performed. Finally, was performed an empirical comparison of proposed time series segmentation algorithms on two types of time series data: stationary (normally distributed data) and non stationary (financial data) in order to check noise robustness of two proposed algorithms. The proposed ISWAB algorithm produces high quality approximations on all types of data and significantly decreases the number of created segments in case of stationary distributed data.

KEY TERMS AND DEFINITIONS

Big Data: Big data usually includes data sets with sizes beyond the ability of commonly-used software tools to capture, curate, manage, and process the data within a tolerable elapsed time.

Data Stream: Data stream is time series sequence which flows into a computer system continuously, in a non-stationary way and with varying update rates. Often, it may be impossible to store an entire data stream or to scan through it multiple times due to its tremendous volume.

Financial Index: A time dependent indicator used to measure and report value changes in a selected group of stocks.

Segmentation: Segmentation refers to the automatic process of partitioning a data stream into multiple segments by set of predefined features (e.g. temperature, electricity consumptions, workdays, etc.).

Sliding Window: Sliding (Rolling) window refers to looking at a subset of points in the time series rather than all previous points. This “window” consecutively rolls back, holding the same number of points within the window as it moves along the time series data streams.

Stationarity: A statistical characteristic of a time series for which the distribution does not change over time.

Time Series: A series of values of a quantity obtained at successive times, often with equal intervals between them.

Challenges for Big Data Security and Privacy

B

M. Govindarajan

Annamalai University, India

INTRODUCTION

Big data refers to collections of data sets with sizes outside the ability of commonly used software tools such as database management tools or traditional data processing applications to capture, manage, and analyze within an acceptable elapsed time. Big data sizes are constantly increasing, ranging from a few dozen terabytes in 2012 to today many petabytes of data in a single data set. Big data creates tremendous opportunity for the world economy both in the field of national security and also in areas ranging from marketing and credit risk analysis to medical research and urban planning. The extraordinary benefits of big data are lessened by concerns over privacy and data protection.

As big data expands the sources of data it can use, the trust worthiness of each data source needs to be verified and techniques should be explored in order to identify maliciously inserted data. Information security is becoming a big data analytics problem where massive amount of data will be correlated, analyzed and mined for meaningful patterns.

Security of big data can be enhanced by using the techniques of authentication, authorization, encryption and audit trails. There is always a possibility of occurrence of security violations by unintended, unauthorized access or inappropriate access by privileged users.

To protect privacy, two common approaches used are the following. One is to restrict access to the data by adding certification or access control to the data entries so sensitive information is accessible to a limited group of users only. The other

approach is to anonymize data fields such that sensitive information cannot be pinpointed to an individual record. For the first approach, common challenges are to design secured certification or access control mechanisms, such that no sensitive information can be misconduct by unauthorized individuals. For data anonymization, the main objective is to inject randomness into the data to ensure a number of privacy goals (Xindong Wu et al., 2014).

BACKGROUND

Today we are living in an era of digital world. With the rapid increase in digitization the amount of structured, semi structured and unstructured data being generated and stored is exploding. Usama Fayyad (2012) has presented amazing data numbers about internet usage like “every day 1 billion queries are there in Google, more than 250 million tweets are there in Twitter, more than 800 million updates are there in Face book, and more than 4 billion views are there in You tube”. Each day, 2.5 quintillion bytes of data are generated and 90 percent of the data in the world today were created within the past two years. The data produced nowadays is estimated in the order of zeta bytes, and it is growing around 40% every year. International Data Corporation (IDC) terms this as the “Digital Universe” and predicts that this digital universe is set to explode to an unimaginable 8 Zetabytes by the year 2015. The above examples demonstrate the rise of big data applications where data collection has grown tremendously and is beyond the ability of com-

monly used software tools to manage, capture, and process.

From a privacy and security perspective, the challenge is to ensure that data subjects (i.e., individuals) have sustainable control over their data, to prevent misuse and abuse by data controllers (i.e., big data holders and other third parties), while preserving data utility, i.e., the value of big data for knowledge/patterns discovery, innovation and economic growth.

Cloud protection alliance big data working group identify top protection and seclusion problems that need to confine for making the big data computing and infrastructure more secure. Most of these issues are linked to the big data storage and computation. There having some challenges which are related to secure data storage (Cloud Security Alliance White paper, 2012). Different security challenges related to data security and privacy are discussed in (A. A. Soofi et al., 2014) which include data breaches, data reliability, data accessibility and data support. Privacy is major concern in outsourced data. Recently, some controversies have revealed how some security agencies are using data generated by individuals for their own benefits without permission. Therefore, policies that cover all user privacy concerns should be developed. Furthermore, rule violators should be identified and user data should not be misused or leaked. The following sections describe some relevant challenges to security and privacy in the context of big data.

MAIN FOCUS

Challenges for Big Data Security and Privacy

With the proliferation of devices connected to the Internet and connected to each other, the volume of data collected, stored, and processed is increasing everyday, which also brings new challenges in terms of the information security. In fact, the currently used security mechanisms such as fire-

walls and DMZs cannot be used in the Big Data infrastructure because the security mechanisms should be stretched out of the perimeter of the organization's network to fulfill the user/data mobility requirements and the policies of BYOD (Bring Your Own Device). Considering these new scenarios, the pertinent question is what security and privacy policies and technologies are more adequate to fulfill the current top Big Data privacy and security demands (Cloud Security Alliance, 2013). These challenges may be organized into four Big Data aspects such as infrastructure security (e.g. secure distributed computations using MapReduce), data privacy (e.g. data mining that preserves privacy/granular access), data management (e.g. secure data provenance and storage) and, integrity and reactive security (e.g. real time monitoring of anomalies and attacks).

Considering Big Data there is a set of risk areas that need to be considered. These include the information lifecycle (provenance, ownership and classification of data), the data creation and collection process, and the lack of security procedures. Ultimately, the Big Data security objectives are no different from any other data types – to preserve its confidentiality, integrity and availability.

Being Big Data such an important and complex topic, it is almost natural that immense security and privacy challenges will arise (Michael & Miller, 2013; Tankard, 2012). Big Data has specific characteristics that affect information security: variety, volume, velocity, value, variability, and veracity. These challenges have a direct impact on the design of security solutions that are required to tackle all these characteristics and requirements (Demchenko, Ngo, Laat, Membrey, & Gordijenko, 2014). Currently, such out of the box security solution does not exist.

Cloud Secure Alliance (CSA), a non-profit organization with a mission to promote the use of best practices for providing security assurance within Cloud Computing, has created a Big Data Working Group that has focused on the major challenges to implement secure Big Data

services (Cloud Security Alliance, 2013). CSA has categorized the different security and privacy challenges into four different aspects of the Big Data ecosystem. These aspects are Infrastructure Security, Data Privacy, Data Management and, Integrity and Reactive Security. Each of these aspects faces the following security challenges, according to CSA:

INFRASTRUCTURE SECURITY

Secure Distributed Processing of Data

Distributed programming frameworks utilize parallel computation and storage to process massive amounts of data. For example, the MapReduce framework splits an input file into multiple chunks. In the first phase of MapReduce, a Mapper for each chunk reads the data, performs some computation, and outputs a list of key/value pairs. In the next phase, a Reducer combines the values belonging to each distinct key and outputs the result. There are two major attack prevention measures: securing the mappers and securing the data in the presence of an untrusted mapper.

Security Best Actions for Non-Relational Data-Bases

The security infrastructures of non-relational data stores popularized by NoSQL databases are still evolving (L. Okman et al., 2011). For instance, robust solutions to NoSQL injection are still not mature. Each NoSQL database was built to tackle different challenges posed by the analytics world, and security was never addressed during the design stage. Developers using NoSQL databases usually embed security in the middleware. NoSQL databases do not provide any support for explicitly enforcing security in the database. However, clustering aspects of NoSQL databases pose additional challenges to the robustness of such security practices.

DATA PRIVACY

Data Analysis through Data Mining Preserving Data Privacy

As described by Boyd and Crawford (2012), Big Data can potentially enable invasions of privacy, invasive marketing, decreased civil liberties, and increased state and corporate control.

A recent analysis of how companies are leveraging data analytics for marketing purposes included an example of how a retailer was able to identify a teen's pregnancy before her father learned of it (C. Duhigg, 2012). Similarly, anonymizing data for analytics is not enough to maintain user privacy. For example, AOL released anonymized search logs for academic purposes, but users were easily identified by their searches (M. Barabard et al., 2006). Netflix faced a similar problem when anonymized users in their data set were identified by correlating Netflix movie scores with IMDB scores.

Therefore, it is important to establish guidelines and recommendations for preventing inadvertent privacy disclosures.

Cryptographic Solutions for Data Security

There are two fundamentally different approaches to controlling the visibility of data to different entities, such as individuals, organizations and systems. The first approach controls the visibility of data by limiting access to the underlying system, such as the operating system or the hypervisor. The second approach encapsulates the data itself in a protective shell using cryptography. Both approaches have their benefits and detriments. Historically, the first approach has been simpler to implement and, when combined with cryptographically-protected communication, is the standard for the majority of computing and communication infrastructure.

However, the system-based approach arguably exposes a much larger attack surface. The

literature on system security is replete with attacks on the underlying systems to circumvent access control implementations (such as buffer overflow and privilege escalation) and access the data directly. On the other hand, protecting data end-to-end through encryption exposes a smaller, more well-defined attack surface. Although covert side-channel attacks (C. Percival, 2005; Aciğmez et al., 2006) are possible to extract secret keys, these attacks are far more difficult to mount and require sanitized environments.

Granular Access Control

The security property that matters from the perspective of access control is secrecy – preventing access to data by people that should not have access. The problem with coarse-grained access mechanisms is that data that could otherwise be shared is often swept into a more restrictive category to guarantee sound security. Granular access control gives data managers more precision when sharing data, without compromising secrecy.

DATA MANAGEMENT AND INTEGRITY

Secure Data Storage and Transaction Logs

Data and transaction logs are stored in multi-tiered storage media. Manually moving data between tiers gives the IT manager direct control over exactly what data is moved and when. However, as the size of data set continues to grow exponentially, scalability and availability have necessitated auto-tiering for Big Data storage management. Auto-tiering solutions do not keep track of where the data is stored, which poses new challenges to secure data storage. New mechanisms are imperative to thwart unauthorized access and maintain constant availability.

Granular Audits

With real-time security monitoring, notification at the moment an attack takes place is the goal. In reality, this will not always be the case (e.g., new attacks, missed true positives). In order to discover a missed attack, audit information is necessary. Audit information is crucial to understand what happened and what went wrong. It is also necessary due to compliance, regulation and forensic investigation. Auditing is not something new, but the scope and granularity might be different in real-time security contexts. For example, in these contexts there are more data objects, which are probably (but not necessarily) distributed.

Data Provenance

Provenance metadata will grow in complexity due to large provenance graphs generated from provenance-enabled programming environments in Big Data applications. Analysis of such large provenance graphs to detect metadata dependencies for security and/or confidentiality applications is computationally intensive.

REACTIVE SECURITY

End-to-End Filtering and Validation

Many Big Data uses in enterprise settings require data collection from a variety of sources, including end-point devices. For example, a security information and event management system (SIEM) may collect event logs from millions of hardware devices and software applications in an enterprise network. A key challenge in the data collection process is input validation: how can we trust the data? How can we validate that a source of input data is not malicious? And how can we filter malicious input from our collection? Input validation and filtering is a daunting challenge posed by untrusted input sources, especially with the bring-your-own-device (BYOD) model.

Supervising the Security Level in Real-Time

These security and privacy challenges cover the entire spectrum of the Big Data lifecycle: sources of data production (devices), the data itself, data processing, data storage, data transport and data usage on different devices.

SOLUTIONS AND RECOMMENDATIONS

There is no single magical solution to solve the identified Big Data security and privacy challenges and traditional security solutions, which are mainly dedicated to protect small amounts of static data, are not adequate to the novel requisites imposed by Big Data services (Cloud Security Alliance, 2013). There is the need to understand how the collection of large amounts of complex structured and unstructured data can be protected. Non-authorized access to that data to create new relations, combine different data sources and make it available to malicious users is a serious risk for Big Data. The basic and more common solution for this includes encrypting everything to make data secure regardless where the data resides (data center, computer, mobile device, or any other). As Big Data grows and its processing gets faster, then encryption, masking and tokenization are critical elements for protecting sensitive data.

The new Big Data security solutions should extend the secure perimeter from the enterprise to the public cloud (Juels & Oprea, 2013). In this way, a trustful data provenance mechanism should be also created across domains. In addition, similar mechanisms to the ones used in (Luo, Lin, Zhang, & Zukerman, 2013) can be used to mitigate distributed denial-of-service (DDoS) attacks launched against Big Data infrastructures. Also, a Big Data security and privacy is necessary to ensure data trustworthiness throughout the entire data lifecycle – from data collection to usage.

The personalization feature of some Big Data services and its impact on the user privacy is discussed in (Hasan, Habegger, Brunie, Bennani, & Damiani, 2013). They discuss these issues in the backdrop of EEXCESS, a concrete project aimed to both provide high level recommendations and to respect user privacy. A recent work describes proposed privacy extensions to UML to help software engineers to quickly visualize privacy requirements, and design them into Big Data applications (Jutla, Bodorik, & Ali, 2013).

While trying to take the most of Big Data, in terms of security and privacy, it becomes mandatory that mechanisms that address legal requirements about data handling, need to be met. Secure encryption technology must be employed to protect all the confidential data (Personally Identifiable Information (PII), Protected Health Information (PHI) and Intellectual Property (IP) and careful cryptographic material (keys) access management policies, need to be put in place, to ensure the correct locking and unlocking of data – this is particularly important for data stored. In order to be successful these mechanisms need to be transparent to the end-user and have low impact of the performance and scalability of data (software and hardware-based encryptions mechanisms are to be considered) (Advantech, 2013).

An important security and privacy challenge for Big Data is related with the storage and processing of encrypted data. Running queries against an encrypted database is a basic security requirement for secure Big Data however it is a challenging one. This raises questions such as:

1. Is the database encrypted with a single or multiple keys;
2. Does the database needs to be decrypted prior to running the query;
3. Do the queries need to be also encrypted; and
4. Who as the permissions to decrypt the database; and many more.

Recently a system that was developed at MIT, provides answers to some of these questions. CryptDB allows researchers to run database queries over encrypted data (Ra Popa & Redfield, 2011). Trustworthy applications that intent to query encrypted data will pass those queries to a CryptDB proxy (that sits between the application and the database) that rewrites those queries in a specific way so that they can be run against the encrypted database. The database returns the encrypted results back to the proxy, which holds a master key and will decrypt the results, sending the final answer back to the application. CryptDB supports numerous forms of encryption schemes that allow different types of operations on the data (RA Popa & Redfield, 2012). Based on CryptDB, Google has developed the Encrypted Big Query Client that will allow encrypted big queries against their BigQuery service that enables super, SQL-like queries against append-only tables, using the processing power of Google's infrastructure (Google, 2014).

Apart from more specific security recommendations, it is also important to consider the security of the IT infrastructure itself. One of the common security practices is to place security controls at the edge of the networks however, if an attacker violates this security perimeter it will have access to all the data within it. Therefore, a new approach is necessary to move those security controls near to the data (or add additional ones). Monitoring, analyzing and learning from data usage and access is also an important aspect to continuously improve security of the data holding infrastructure and leverage the already existing security solutions (Kindervag et al., 2012; Kindervag, Wang, Balaouras, & Coit, 2011).

FUTURE RESEARCH DIRECTIONS

Big data is a conventional term used to describe the exponential increase and accessibility of structured and unstructured data. In future big data will be essential to business as well as so-

ciety like internet facility. Resolutions that were previously build on estimation or on conceptual models of reality can now be done based on the collected and stored data itself. Big Data analysis is now used in almost every phase of our society, communication services, marketing, banking and research. The big data phase has shown the ways for huge opportunities in science, health care system, economic decision, educational system and novel forms of public interaction and entertainment. But these opportunities also result in challenges in the area of privacy and security.

There are also important research challenges on maintaining end to end data security and privacy. Ensuring that data is never revealed in clear, in particular to non-authorized parties, on any point of the Big Data lifecycle. Moving from data to programs, there are techniques for protecting privacy in browsing, searching, social interactions, and general usage through obfuscation methods. However, there is more research to be conducted on the processing of encrypted data and privacy protection in the context of both computer programs and web-based systems.

CONCLUSION

In this chapter, the security and privacy problems have been highlighted that need to be addressed to make Big Data processing and computing infrastructure more secure. Common elements specific to Big Data arise from the use of multiple infrastructure tiers (both storage and computing) for processing Big Data; the use of new compute infrastructures such as NoSQL databases (for fast throughput necessitated by Big Data volumes) that have not been thoroughly vetted for security issues; the non-scalability of encryption for large data sets; the non-scalability of real-time monitoring techniques that might be practical for smaller volumes of data; the heterogeneity of devices that produce the data; and the confusion surrounding the diverse legal and policy restrictions that lead to ad hoc approaches for ensuring security and

privacy. Many of the items in this list serve to clarify specific aspects of the attack surface of the entire Big Data processing infrastructure that should be analyzed for these threats.

Throughout this chapter it was possible to present some of the most important security and privacy challenges that affect Big Data projects and their specificities. Although the information security practices, methodologies and tools to ensure the security and privacy of the Big Data ecosystem already exist, the particular characteristics of Big Data make them ineffective if they are not used in an integrated manner. This chapter also presents some solutions for these challenges, but it does not provide a definitive solution for the problem. It rather points to some directions and technologies that might contribute to solve some of the most relevant and challenging Big Data security and privacy issues. As noted throughout this chapter, although some important steps are being given towards solving Big Data security and privacy issues, there is still a long road ahead.

KEY TERMS AND DEFINITIONS

Analysis: Finding tractable solutions based on the threat model.

Big Data: Big data is a conventional term used to describe the exponential increase and accessibility of structured and unstructured data.

CSA: Cloud Secure Alliance, a non-profit organization with a mission to promote the use of best practices for providing security assurance within Cloud Computing, has created a Big Data Working Group that has focused on the major challenges to implement secure Big Data services.

Distributed Programming Frameworks: It utilize parallel computation and storage to process massive amounts of data.

IDC: International Data Corporation terms this as the “Digital Universe” and predicts that this digital universe is set to explode to an unimaginable 8 Zetabytes by the year 2015.

Implementation: Implementing the solution in existing infrastructures.

SIEM: Security information and event management system may collect event logs from millions of hardware devices and software applications in an enterprise network.

How Visualisation and Interaction Can Optimize the Cognitive Processes Towards Big Data

Antonio Feraco

Fraunhofer IDM@NTU, Singapore

Marius Erdt

Fraunhofer IDM@NTU, Singapore

INTRODUCTION

Visual analytics is the study of transformation of data to visual representations. The goal is to create these representations in such a way that their interpretation is driven by effective and efficient cognitive processes that enable an easy understanding of the data itself. Today, visualization and visual analytics is more than just a collection of plots, graphs, and computer-generated 3D renderings. There are many visualization techniques for every form of data, including, but not limited to, texts, documents and corpora, tree graphs and networks, image collections and videos, time series, tabular and multivariate data, geographical data, scalar vector, and tensor fields, isosurfaces, numerical, geometrical, statistical and other mathematical models, historical events and provenance records, dynamic data streams, algorithms, programs, and computational logs, and a wide range of domain-specific data in disciplines such as engineering, biology, medicine and many others.

Visualization is easily perceived as a means for presenting beautiful computer generated images and animations to impress an audience. However, significant evidence obtained through perceptual studies and user evaluation confirms that proper visualization has enabled researchers and decision makers to be more efficient in gaining insights from data and therefore efficiently improving their cognitive system. It facilitates the formulation of new hypotheses, assists in decision-making,

enables effectual communication of ideas, and facilitates dissemination of knowledge.

To gain insight into these data, to make sense of these data, and to gain new scientific knowledge out of it, we must proceed to work on and aim to define efficient and user-friendly solutions.

The importance of having proper visualisation solutions to improve and optimize the memorizing processes is continuously increasing, e.g. to optimize time and effort in cognitive learning processes and in gaining insights from geo-spatial, behavioral, commercial, scientific data.

Useful data is generated with the advent of new hardware technologies and with sensors embedded everywhere. Examples are CCTV cameras, social media, and systems where machines and users generate contents in various forms, such as, videos, images, text and geospatial data. This data represents a valuable source to identify trends in all sectors. Leveraging social media data presents many challenges: social media data has a large volume; it is a multimodal set of data, it is often ambiguous in its content, and is highly context- and user-dependent.

Moreover, Human Computer Interaction (HCI) transformed the way end users are interacting with information. New interaction paradigms, such as voice recognition, gesture based interactions and multi-touch interaction now enable a deeper interactive experience in memorizing information and in optimizing search for information.

DOI: 10.4018/978-1-5225-2255-3.ch034

Mobile platforms like smart phones and tablets have advanced significantly in the last 10 years. The incorporation of faster processors and mobile GPUs has greatly increased the impact and range of applications. The ubiquity of geo data and mapping applications for smart phones has familiarized a broad base of users with the navigation and interpretation of 2-D maps as well as 3-D maps that have been introduced on the major mobile platforms. This phenomenon is also increasing the familiarity of users with navigating in 3-D textured environments not only representing geographical spaces.

The following chapter describes the transformation of cognitive processes through different ways of interacting with data as well as it describes the importance that visualisation is gathering as a common taxonomy to optimize insights from disseminating and sharing data. Its structure is as follows:

1. The first part focuses on the Human Computer Interaction and Interactive Digital Media,
2. The second part focuses on Big Data and Interaction, and
3. The last part comprises of the description of the experiment and the authors conclusions.

The chapter is structured as follows:

1. A first part focuses on the Human Computer Interaction and Multi model user interfaces,
2. The second part on Interaction,
3. The last part comprises of the results from an experiment and the authors conclusions.

BACKGROUND: HUMAN COMPUTER INTERACTION AND MULTI-MODAL USER INTERFACES

To define HCI is not a simple task because of the applicative nature that this subject has and the continuous changes it is facing. Simply, we

can assert that HCI tries to model and analyze the relation between man and computer where the element “computer” changed its nature drastically in the last decades following a very rapid dynamic of change¹. Twenty-five years ago, few people would have anticipated the tremendous processing speed of contemporary computer systems. Even though major improvements have been made in many areas regarding HCI, important issues still remain (Szameitat et al., 2009). HCI studies very heterogeneous objects such as Personal Computers (PC), Personal Digital Assistant (PDA), Mobile Phones, but even simpler objects such as watches or electrical furniture as well as the technologies related to Internet or even more complex technological issues such as the control panel of a chemical plant, the plane cabin, and other. According to the Association for Computing Machinery (ACM) the definition of Human Computer Interaction is:

Human-computer interaction is a discipline concerned with the design, evaluation and implementation of interactive computing systems for human use and with the study of major phenomena surrounding them.

There are other disciplinary points of view that would place the focus of HCI differently than computer science does - just as the definition of databases would be different from a computer science vs. a business perspective. HCI at large is an interdisciplinary area. It is emerging as a specialty concern within several disciplines, each with different emphases: computer science (application design and engineering of human interfaces), psychology (the application of theories of cognitive processes and the empirical analysis of user behavior), sociology and anthropology (interactions between technology, work, and organization), and industrial design (interactive products). From a computer science perspective, other disciplines serve as supporting disciplines, much as physics serves as a supporting discipline for civil engineering, or as mechanical engineering serves as

a supporting discipline for robotics. A lesson learned repeatedly by engineering disciplines is that design problems have a context, and that the overly narrow optimization of one part of a design can be rendered invalid by the broader context of the problem. Even from a direct computer science perspective it is advantageous to frame the problem of human-computer interaction broadly enough such as to help practitioners to avoid the classic pitfall of design that is separated from the context of the problem. Human-computer interaction arose as a field from intertwined roots in computer graphics, operating systems, human factors, ergonomics, industrial engineering, cognitive psychology, and the systems part of computer science. Computer graphics was born from the use of Cathode Ray Tube (CRT) and pen devices very early in the history of computers. This led to the development of several human-computer interaction techniques. Many techniques date from Sutherland's Sketchpad Ph.D. thesis (1963) that essentially marked the beginning of computer graphics as a discipline. Work in computer graphics has continued to develop algorithms and hardware that allows the display and manipulation of ever more realistic-looking objects (e.g., CAD/CAM machine parts or medical images of body parts). Computer graphics has a natural interest in HCI as "interactive graphics" (e.g., how to manipulate solid models in a CAD/CAM system). Furthermore it is an ubiquitous and indispensable tool for industrial design, being the primary means for modeling and communicating product design proposals (Sener et al, 2008). Many disciplines flow together in HCI, but all of them study a common issue. This issue is the digital interactive system placing HCI on the cross road among all these disciplines. Between these disciplines we can name the computer graphics, the cognitive psychology, the design, the economical studies and the economical processes management. In reality, this multi-disciplinary nature derives from the ergonomics both for the physics aspects and the cognitive aspects. The International Ergonomics Association defines ergonomics as:

Ergonomics (or human factors) is the scientific discipline concerned with the understanding of interactions among humans and other elements of a system, and the profession that applies theory, principles, data and methods to design in order to optimize human well-being and overall system performance.

B

The difference between HCI and ergonomics is given by the different emphasis on the various aspects of the interaction human-system. We could think about the HCI as a studying the relationship existing between users and computer systems. A great deal of specifically directed work has taken place over the years, but there are excellent introductory books to HCI (Baecker, Grudin, Buxton, & Greenberg, 1995); (Helander, Landauer, & Prabhu, 1997) and also to the more specific study of user-interfaces as well as the development of new generation interactive interfaces (Feraco, 2016). In HCI there are a great number of approaches used in analyzing computer systems. Of particular importance from early in the discipline's history is the use of cognitive psychological models of user's action and planning to discuss how they interact with computers. Theoretical framework such as the GOMS (Goals, Operators, Methods, Selection rules) approach or Donald Norman's seven-stage action cycle in the Design of everyday things is representative of this tradition. HCI has traditionally used a methodology of building software and user-interfaces, testing them on users, measuring and analyzing the results, improving the software, and so on. In recent times, the popularity of ethnographic techniques such as interviews, observation in workplaces, and so on, has been growing as researchers become more concerned with the context of use. Jakob Nielsen has popularly defined usability as focusing on five main properties for emphasis in software: learnability, efficiency, memorability, error prevention, and user satisfaction. According to ISO 9241-11 (1998), usability is concerned with the effectiveness, efficiency and satisfaction with which user can achieve specified goals in specified context

Figure 1. Context and Use of HCI

Source: Pearce 1994

of use. According to (Preece, Rogers, & Sharp, 2002) the terms effectiveness means “how good a system is at doing what it is supposed to do”. That is, effectiveness suggests that specified goals are to be achieved with accuracy and completeness (ISO 9241-11). Effectiveness is thus related to a system’s desired functionality. Some of the interrelationships among these topics are represented in Figure 1. Computer systems exist within a larger social, organizational and work milieu (U1). Within this context there are applications for which we wish to employ computer systems (U2). But the process of putting computers to work means that the human, technical, and work aspects of the application situation must be brought into fit with each other through human learning, system tailor-ability, or other strategies (U3). In addition to the use and social context of computers, on the human side we must also take into account the human information processing (H1), communication (H2), and physical (H3) characteristics of users. On the computer side, a

variety of technologies have been developed for supporting interaction with humans: Input and output devices connect the human and the machine (C1). These are used in a number of techniques for organizing a dialogue (C2). These techniques are used in turn to implement larger design elements, such as the metaphor of the interface (C3). Getting deeper into the machine substrata supporting the dialogue, the dialogue may make extensive use of computer graphics techniques (C4).

Among the HCI, one of the main aim of the research has been to humanize the interfaces. Humanization of interfaces has two aspects: to simplify interfaces in order to make them easier and pleaser to be used (Schneiderman, 1992; Norman & Draper, 1966) and to make the interfaces the more possible it was similar to human being. The way, among communication human-computer, can be defined as a perceptive process through one of the three channel of human perception. To design effective multi modal interfaces it is good to follow some suggestions given by the

Table 1. Performing the four basic manipulation tasks using four popular input modes, ranked from the easiest (1) to the most difficult (4)

Content Manipulation Task	Voice Mode	Pen Mode	Keyboard/Keypad	Mouse/Joystick
Select objects	Speak the name of the object (3)	Point to or circle the object (1)	Press keys to position the cursor on the object and press the select key (4)	Point to and click on the object or drag to select text (2)
Enter text	Speak the words in the text (2)	Write the text (3)	Press keys to spell the words in the text (1)	Spell the text by selecting letters from a soft keyboard (4)
Enter symbols	Say the name of the symbol and where it should be placed. (3)	Draw the symbol where it should be placed (1)	Enter one or more characters that together represent the symbol (4)	Select the symbol from a menu and indicate where it should be placed (2)
Enter sketches or illustrations	Verbally describe the sketch or illustration (2)	Draw the sketch or illustration (2)	Impossible (4)	Create the sketch by moving the mouse so it leaves a trail (similar to an Etch-a-Sketch™) (3)

Source: W3C Group Note

W3C organizations; these suggestions are based on four major principles:

1. Satisfy real-world constraints.
2. Communicate clearly, concisely and consistently with users.
3. Help users recover quickly and efficiently from errors.
4. Make users comfortable.

What the user is willing to achieve through the application is limited by the real-world constraints. These limitations may be due to the nature of the task the user intend to perform, other activities the user is performing, physical limitations of the user, and condition of the environment in

which the user is performing the task. The user interface should be designed to compensate for these limitations. The tasks mostly performed by the users are indicated in Table 1, and those tasks are mostly achieved through the use of the new mobile devices that will enable to enter data by speaking into a microphone, writing with a stylus, and pressing keys on a small keypad.

It is needed to take in account even the physical suggestion thus physical devices exhibit different usability characteristics. The size, the shape and the weight of the device affect how it may be used. Most important, the placement of a microphone and speaker, the size of the display and writing surface, and the size of keys in a keypad affect the ease with which a user can enter information

Table 2. Physical usability issues for the four most popular modes of information entry

Device Usability Issues	Voice Mode	Pen Mode	Keystrokes Mode	Mouse/Joystick Mode
Required number of user hands	None (plus possibly one to hold the device)	One (plus possibly one to hold the device)	One or two	One
Required use of eyes	No	Yes	Frequently, but some users can operate familiar keyboards without looking at them	Yes
Portable	Yes, especially when walking	Yes, but difficult while walking	Yes, but difficult while walking	Yes, but difficult while walking

Source: W3C working group note

by speaking, writing or pressing keys. Table 2 summarizes the three modes of respect to physical usability issues.

Another important issue to consider is the one related to the environment. People may work in environment that may not be ideal for some modes of user interfaces. The environment might be noisy or quiet, hot or cold, light or dark, or moving or stationary with a variety of distractions and possible dangers. Multimodal user interfaces must be designed to work in the environments where they will be used. Table 3 summarizes the environmental usability issues with respect to four popular input modes.

The second principle on which these suggestions are based is the clear, concise and consistent communication with the user. Effective communication between the user and the device is necessary for achieving the user's goals. The MUI (Multimodal User Interface) is the conduit for all communication between the user and the device. Communication has to be clear and concise, avoiding ambiguities and confusion. Communication styles should be consistent and systematic so users know what to expect and can leverage the patterns and rhythms in the dialog. This can be achieved through consistency suggestions that will enable users to leverage conversational patterns to accelerate their interaction, through organizational suggestions thus organizing information and transition between topics will improve the users' comprehension of and performance with the multimodal interface; information should be structured and organized as in ways that are familiar to the user. The third principle is to help users recover quickly and efficiently from errors, in fact all users,

especially novice users, will occasionally fail to respond to a prompt appropriately. The UI must be designed to detect such errors and assist user to recover naturally, furthermore the multimodal interface should help users learn how to use the user interface to achieve the desired results quickly and efficiently. This could be achieved through the conversational inputs, in fact the principle of conversational discourse advice that the suggestions for the nature, content and format of information exchanged between two humans may be applied to information exchanged between a human and a computer; through reliability, that is a lot frustrating for the user having a device at hand and not being able to use it. The last principle is to make users feel comfortable; users often judge a computer application by its user interface. If they will not like the user interface, the application will not be used. If the user interface is not easy to learn and not easy to use, the application cannot be used successfully.

Three different way can be chosen: visible, listenable and touchable. With the advances in ubiquitous computing the quest for natural interaction is of utmost importance. This includes interaction with different devices and modalities that are optimally suited to support the user's tasks, ideally without requiring the user to select and configure such devices. A multimodal/multi-device media player application is sketched by (Schaefer & Mueller, 2008) and summarized in Figure 2.

A user can employ different devices to control the media player such as a mobile phone, the media-playing device itself, a microphone for voice control or a wireless multisensory for gesture interaction. When we consider the

Table 3. Environmental usability issues for the four popular modes of information entry

Device Usability Issues	Voice Mode	Pen Mode	Keystroke Mode	Mouse/Joystick Mode
Noisy environment	Works poorly in a noisy environment	Works well in a Noisy environment	Works well in a noisy environment	Works well in a noisy environment
Other environmental concerns	Works well independently of gloves	Does not work well when users must wear thick gloves	Does not work well when users must wear thick gloves	Does not work well when users must wear thick gloves

Source: W3C working group note

Figure 2. A multimodal/multi-device media player

Source: Schaefer and Mueller, 2008

Interactive Digital media, we have to care about the ubiquitous computing environments. In this environment an increasing number of services are delivered to users through various devices including cellular phones and PDAs (Portable Digital Assistant). Then, it is important to facilitate interoperability among services on these heterogeneous and autonomic environments. Web services (Ferris & Farrel, 2003) based on Internet standards such as SOAP (Simple Object Access Protocol) (Mitra & Lafon) and WSDL (Web Service Description Language) gained a momentum as a standard interface for the interoperability between software applications. This led literature to deepening studies related to the understanding individuals' motivation and involvement. It is of a central concern in media uses and effects research, because it is more illuminating to reveal why and how people use media rather than just to focus on what people do with media.

BIG DATA

It is worth to provide the reader with a brief description also about Big Data and the related challenges, to introduce then the impact that

visualisation and interaction might have on the learning cognitive processes.

According to Wikipedia Big Data is a term for *data sets* that are so large or complex that traditional data processing applications are inadequate to deal with them. Challenges include analysis, capture, data curation, search, sharing, storage, transfer, visualisation, querying, updating and information privacy. The term Big Data often refers simply to the use of predictive analytics, user behavior analytics, or certain other advanced data analytics methods that extract value from data, and seldom to a particular size of data set (Cavanillas, Curry, & Wahlster, 2015).

According to (Cavanillas, Curry, & Wahlster, 2015) Big Data is also the emerging field where innovative technology offers new ways of extracting value from the huge fluxes of information coming from heterogeneous sources. Today's environment allows us to have access to more types of data which comes in all kind of forms: from highly structured ERP (Enterprise Resource Planning) data, or CRM (Customer Relation Management) data, to multi-million text file, to video files and machine generated sensor data and BIM (Building Information Management) data. The data sources include online transactions, social networking ac-

tivities, mobile device services, internet gaming, conceptualization and design and etc.

In line with it, data sources are expanding, not only coming from social networks sources, such as Facebook, YouTube, Google (Shen, Li, Wu, & Liu, 2016), but also from the Digital Transformation the most of the sector are facing, from the most traditional, like medical and constructions, to the newest ones, e-commerce and Fintech.

The amount of Heterogeneous and multidimensional datasets is most of the times not easy to be analyzed. In many domains experts are striving to make sense out of data which is collected and computed through several sources, mainly why there is a boom in the amount of information that can be produced per sample (Turkay, Lundervold, Lundervold, & Hauser, 2013).

In this context, HCI, as well as HMI (Human Machine Interaction) gain exponential importance, above all considering the nowadays interaction methodologies with handheld devices and the technology trend of moving towards a keyboard-less based human data interaction. Among these consideration, visualisation also start to play a key role in the discipline of Human Data Interaction.

VISUALISATION

Not far in the past, the ability to create smart data visualisation (or aka “Data-Viz”) was a simple nice-to-have skill for design- and data-minded managers. Nowadays it became a must have skill for all software managing big datasets (Berinato, 2016). Decision makers increasingly relies on data, which are characterized by the high pace of their generation, velocity and huge volume, leading to some level of abstraction in most of the cases. In the context of this chapter, Visualisation is defined by the common taxonomy to understand big datasets. We entered a data-driven era, not only from the data generation perspective, but also from the growing expectations placed in the analysis of data. On a parallel path, graphic cards together with their imaging processing power can

leverage large data visualisation but they can also be of great interest to support interaction (Hurther, 2016). One of the main technique used in data visualisation is the image based one. This approach takes advantage of changes in the bottlenecks of computer graphics: since data storage and memory limitation is becoming less and less of an issue (Sutherland, 2012). Main instances of image-based techniques with the graphic card usage to facilitate multivariate data exploration are:

- **Rendering:** Graphics card can now render numerous items on the screen and thus can display large datasets.
- **Computation:** Graphic cards can perform fast and parallel data processing, and can be used to process information at the data level.
- **Interaction:** Interaction with the data is an important manipulation paradigm to perform data exploration. Graphic cards can be used to provide tools to help users to interact with large data sets.

THE INTERACTIVITY IN DIGITAL MEDIA

As big data are at the base of digital media, most of digital media are based on the principle of interactive structures. User should be able to relocate and to challenge them-selves to the interactive observation of a work. All projects and/or development related to digital media should excite not only the visitors’ bodies, but also should bring their thoughts into motion. Becoming part of an interactive work, for the user, “Touching” an interactive work is not only allowed, but becomes necessary; whether with mouse, trackball, touch screen, tangible objects, video camera, responsive workbench, virtual balance, the touch less Point-Screen or other interfaces; the observer should be conducted to bring the process into motion (Fleischmann & Strauss, 2008), (Feraco, 2016). In the field of arts, digital media, and even more

interactive digital media, represents a milestone of the new challenges. Many researches tried to define interactivity, underlining its importance and focusing it on differences existing in perception (Johnson & Kaye, 2016). The difference in perception is differentiated as follows: “A painting is an instance of representation. A film is a sequence of representation. Interactive artworks are not an instance of representation; they are virtual machines which themselves produce instances of representation based on real time inputs”. According to (Valli, 2008) interaction design is the art of instigating and guiding behaviors (or interaction design) by means of proper static or dynamic stimuli. It is defined in terms of experiences: people naturally communicate through gestures, expressions, movements, and discover the world by looking around and manipulating physical stuff. Valli also states that the key assumption here is that they should be allowed to interact with technology as they are used to interact with the real world in everyday life, as evolution and education taught them to do. Because of these assumptions today’s designers face a great challenge: the creation of new interaction paradigms and new media conventions, that exploit the new machines’ sensing capabilities offered by technology and to take care of human spontaneous ways to discover the real world. On the other side, interactive technology, in terms of sensors, actuators and narrative intelligence, is still matter of research for engineers and scientists. As even stated by (Fleischmann & Strauss, 2008) interactive structures remain the basic principle of digital media. Users of digital media will be in a position to relocate and to challenge themselves to the interactive projects to make an experience that moves over and beyond the usual contemplative observation.

Based on the state of the art before mentioned Fraunhofer IDM@NTU, in Singapore, develops interactive user interfaces that enables a smoother interaction between the user himself and big datasets. Following is described an approach to the study of one of the technologies developed that strengthen the importance of three key dimensions for interactive digital media:

1. Efficiency,
2. Experience, and
3. Usability.

TAM STUDY OF A BUILDING INTERACTIVE 2D MAP AND A 3D WALKTHROUGH

BIM (Building Information Models) represents a big dataset in the building and construction industry. Their visualisation is not always smooth and simple for non-experts, consequently in this specific area the adoption of interactive technologies, i.e. interactive walkthrough, can represent a technique enabling a faster acquisition of data insights. In this context the author shares a Technology Acceptance Model study conducted during SIGGRAPH Asia 2014 in Singapore and its results gathered where three main dimensions: experience, efficiency and usability, related to the interaction with a 2D map allowing a 3D navigation walk through have been analyzed. To simplify the description of the overall set-up, including both the hardware (a 46” multi-touch table and a 55” vertical UHD TV) and the User Interface have been given the acronym of MTT. The core characteristics of both the technologies used for the TAM study are based on visualisation and interaction paradigms.

The study focused on understanding the impact on tasks given to the users of three different dimensions and their respective factors:

- **Experience, Factors Related:** Engaging and Intuitiveness.
- **Efficiency, Factors Related:** Reliability of the touch (precise and sensitive), User friendly (easy to locate myself in the map).
- **Usability, Factors Related:** 3 fingers related function, maps switching, multi-map manipulation, usefulness for multi-collaborative purposes.

Each end-user was given specific tasks in two different maps:

1. The Siena Cathedral, and
2. The Frankfurt Messe.

Both maps and 3D environment are a virtual representation of the real

1. Cathedral in Siena, and
2. The building used in Frankfurt to conference and events.

The study has been conducted on four different categories of people: Computer Graphics experts, Computer Science experts, Students, and Media.

Figure 3 summaries the model outcome of the analysis:

Figure 3 shows that Usability is dimension that impacts the most on the UI developed and that also has major influence on the others. In this

specific context usability has been developed on top of Visualisation and interaction paradigm that simplified and enhanced the cognitive processes and the task accomplishment of the end users.

FUTURE RESEARCH DIRECTIONS

More and more UI are being developed with in mind the main paradigm of usability, user friendliness and intuitiveness, but there is still the need to improve and to further analyze the overall Human Data Interaction considering that the trend to optimize both time and space is leading us towards a keyboard-less world where touch based interactions are becoming the main mean of querying for data insights.

Figure 3. Model resulting from the TAM study

CONCLUSION

The study further proved that visualisation and interaction flow into optimizing the usability of a multimodal user interface. Visualisation on its own can be regarded as the new taxonomy to communicate with the information while interaction as the query generator.

Technologies such as virtual reality and augmented reality are now facing a breakthrough in the market, and their fields of application are growing exponentially. Nevertheless, in this specific fields, as well as in the computer graphics in general, expertise and experience plays a key role to design and implement at the best the usability in relation to the scope the UI is made for.

Nowadays, more than in the past, the capability of merging visual expertise and interaction consciousness are the basic breakthrough for any application to be successful in the end-users' acceptance environment.

KEY TERMS AND DEFINITIONS

Big Data: Is a term for data sets that are so large or complex that traditional data processing applications are inadequate.

Cognitive Process: The performance of some composite cognitive activity; an operation that affects mental contents; “the process of thinking”; “the cognitive operation of remembering”.

Efficiency: The ratio of the output to the input of a given system. Efficiency is measured as the resources expended by the user in relation to the accuracy and completeness of goals achieved (ISO standard 9241).

Ergonomics: Is the scientific discipline concerned with the understanding of interactions among humans and other elements of a system, and the profession that applies theory, principles, data and methods to design in order to optimize human well-being and overall system performance”.

Human Computer Interaction: HCI (human-computer interaction) is the study of how people interact with computers and to what extent computers are or are not developed for successful interaction with human beings.

Interactive Walkthrough: The possibility to digitally interact with a 2D map and visualizing the 3D environment.

Usability: The degree to which a software can be used by specified consumers to achieve quantified objectives with effectiveness, efficiency, and satisfaction in a quantified context of use.

Visualisation: Making a visible presentation of numerical data, particularly a graphical one.

B

Managing and Visualizing Unstructured Big Data

Ananda Mitra

Wake Forest University, USA

INTRODUCTION

This essay expands on the notion of “Big Data” to open up alternative analytic opportunities, on certain components of the data, through a theoretical lens that is mobilized to offer an interpretation and visualization of the information contained in large amounts of data. It is useful first to examine the term “Big Data” in some detail. The term refers to a phenomenon which results from the fact that institutions and individuals are digitizing many different kinds of information leading to an exponential growth of the amount of data that is being stored in the digital space. First, this expansion relates to the *increase in data points* as more records are added to the corpus of Big Data. Second, the idea of Big Data needs to be considered in terms of the *details that are being digitized*. The notion of Big Data should be considered both in terms of the breadth of the data in terms of number of data points (*amount*) and the depth of the data related to the various fields of information available for each record (*details*). Therefore, Big Data has become an object of analysis for a variety of groups, from academics to marketers, all of whom are interested in understanding how Big Data could provide highly granular voluminous information about people (see, e.g., Mitra, 2014c). Next, it is useful to examine the different categories of information that makes up “Big Data.”

Much of Big Data is numeric that is amenable to mathematical analysis. For instance, it is possible to easily count the number of tweets produced by an individual. Such counts offer the opportunity

for companies such as Tweeter to offer information about what topics are popular at any moment in time. The segment of Big Data that offers the ease of analysis and visualization has been called “structured” Big Data. There is, however, another vast component of Big Data that does not allow for easy numeric analysis. This segment is made up of the utterances of the people who are self-generating the Big Data by voicing themselves in the digital space. An example of this segment of Big Data is the actual specific tweet produced by an individual or the specific photograph uploaded on photograph sharing spaces. In the case of the tweet, the language of the tweet contains information about attitudes and opinions, just as a photograph offers information about the individual who has captured the picture. This form of data requires a more nuanced and “qualitative” analytic process that would discover the intent of the authors and the meanings of the messages encapsulated in a microblog or picture. This segment of Big Data has been named “unstructured” Big Data. Not only is it difficult to analyze the unstructured Big Data but it is also difficult to visualize the findings of analysis. The qualitative process does not typically produce convenient charts and graphs. The analysis needs to be offered for easier understanding and unstructured Big Data makes this a challenge as well.

This paper offers a theoretical and analytic process to consider ways of analyzing Big Data and visualizing the analysis. To do this, it is important to offer a theoretical basis to consider the elements of unstructured Big Data.

BACKGROUND

Perspective on Big Data

The unstructured Big Data can be categorized into three main types. The first set are characterized by short word length where the information is authored by individuals and institutions. This form of the data has sometimes been called “micro-blogs,” as reference to blogs that are strictly restricted by the number of words that can be used in the discourse. The most popular example of micro-blogs are the statements produced by the users of the computer program called Tweeter. The second set of unstructured Big Data is an extension of micro-blogs where the restriction on size disappears but all the other characteristics remain intact. This is a situation where a user can generate discourse of significant length and place it in a digital repository. One popular example of this category are “posts” that users upload within their Facebook “profiles.” The third category of unstructured Big Data that is worthy of consideration is discourse that users generate in response to specific queries. This form of data is rarely circulated over the Internet, but remains as in-depth lengthy treatise on very specific issues that the user is prompted to elaborate. Much like the second category, this segment of unstructured Big Data is not usually restricted in length. However, there are greater restrictions on the scope of content of this form of data since a majority of this data is generated in response to prompts and questions. A good example of this form of data are responses to open-ended questions used in questionnaires in varieties of data collection projects ranging from measuring political opinions to public health assessments. This three-pronged categorization encompasses the majority of unstructured Big Data with one common characteristic – the data is user-generated. It is therefore useful to consider how to characterize the author of the discourse. I offer two broad categories, which can be considered to be mutu-

ally exclusive for most considerations. The two user groups are “institutions” and “individuals” with the differentiating factor being the level of agency of the user.

Institutions often bring the full force of their creative, financial and cultural capital to the creation of digital data, often in the form of “home pages” that populate the digital space. This form of data represents an “authoritative” voice of the powerful and dominant within the public sphere (Foucault, 1991). Such voices carry the ideological baggage of the institutions and their relative position along a continuum of power from the dominant to the oppositional. However, with the availability of the digital tools and the relative ease with which digital data can be produced and circulate it is increasingly possible for some individuals to create such home pages which represented the voice of the relatively powerless individual who would not have the institutional support to present themselves in the public sphere (see, e.g., Mitra and Watts, 2002; Mitra, 2011). Starting with home pages, individuals were able to gain a sense of agency and authorship in the digital space where the individual user-generated data was beginning to become available in the digital space. This tendency expanded rapidly with the development of better tools for digital communication and the ease with which individuals could constantly generate data and place it within networks of other users who were also generating data. Consequently, a new state of empowerment was being achieved by the individuals where their voice was becoming alongside the authoritative voices of the institutions. The corpus of Big Data is thus made up of the institutionally produced and individually authored information. In the remainder of the essay, the focus is on the three categories of Big Data – micro-blogs, posts, and response to open ended questions – produced by individuals. In the next section a specific theoretical approach is suggested to help analyze this form of data.

B

Narrative Theory and Narbs

One of the key characteristics of the people who are producing the unstructured Big Data is that they are individuals without any specific claims of authority, in contrast to the authoritative voice of the institutions. For example, in the last quarter of 2015, 1.59 billion users had logged into Facebook at least once in the past thirty days (Facebook users worldwide 2016, n.d.). Even if a portion of these active users would have created a small Facebook “post” by stating what they have done, what they think about something, or any other personal information, then the individual has contributed to the creation of unstructured Big Data. This form of personal information has been defined as a narb which, “is short for “narrative bit,” a snippet of personal information about your life that you’re willing to share with others (Zimmer, n.d.).”

The key to this definition is the notion of narrative (Mitra, 2014b). It has been suggested that unstructured Big Data is indeed made up of narratives or stories that individuals are now empowered to tell about themselves. It has been argued that people are fundamentally story-telling beings. This has been maintained by scholars across many disciplines where it has been suggested that along with being rational beings at times, rhetorical beings at moments, human beings are also narrative beings. As a narrative being, humans make sense of the World around them through the stories that they tell, and the stories that they listen to (Fisher, 1982, 1984, 1985a, 1985b, 1987). A simple illustration of this story telling process is the way in which interpersonal interactions typically start between strangers with a simple, but profound question – “where are you from?” In the response to the question lies an entire narrative of a person’s life, and the way in which an individual chooses to respond, depending on context and one’s history, produces, in the voice of the individual, a personal story. When such stories are carried over to the digital spaces such as those of digital networks, those stories operate as the narbs that make up unstructured Big Data.

The opportunity to characterize these narbs as building blocks of large stories also acts as the point of departure to place these narbs within the larger framework of narrative theories, most notably the theoretical approach that argues for a “narrative paradigm” to consider the way everyday life operates. Just as there are paradigms that argue for rationality, the narrative paradigm proposed by Walter Fisher suggests that the analysis of the stories offer an understanding of the elements of the story in terms of its believability and aesthetic structure. When the theory was first proposed, the motives of the authors in telling the story were of less importance than the structure of the stories themselves. However, the paradigm offered both a theoretical and methodological possibility of considering the stories as the indicator of the motives of the authors in telling the stories. This opportunity was also not used because a good portion of the stories available for analysis in the mid-1980s were non-biographical stories. Consider any of the tragedies authored by Shakespeare. These are not stories that tell the life story of the author himself, but the author’s perspective on real and fictional moments in history. While the analysis of the stories would offer a tangential look at the perspective of the author, that was not the main goal of the analysts who were working within the theoretical umbrella of the narrative paradigm. Yet, with the advent of the narb, and its explosive growth as un-structured Big Data, the majority of the narbs are stories uttered by the author about the author.

This is well illustrated in the way that Facebook invites the active user to interact within the digital network. The opening page of the system states, “What’s on your mind?” This is an unambiguous invitation to create a narb about the self. When countless narbs become available - through the three categories discussed earlier in this essay - these narbs become the wealth of stories that can now be analyzed precisely because the narrative paradigm has successfully theorized and argued that humans are narrative beings and by listening to their narratives we learn about people (Mitra,

2012b). The challenge posed by unstructured Big Data is the fact that the volume of narratives has become so large that there must now be specific analytic strategies that need to be utilized for the analysis and visualization of the narbs.

Methodology

There are several aspects in the analytic process that pose challenges. The first challenge relates to the volume of data. Very large amounts of data must be analyzed so that a narrative can be obtained from the large corpus of narbs to obtain the narrative that the narbs collectively tell. In the analytic process used in the method proposed here, this process begins with the identification of narrative categories that make up the narrative. The term “narrative categories” refer to the different components of a story. These components have been identified by narrative analysts and could include elements such as the protagonists of the narrative and the roles the characters play, the actions of the characters, the feelings of the characters towards different issues that are addressed in the narrative (see, e.g., Barthe, 1975; Propp, 1968; Todorov, 1977). The process of creating the narrative from the narbs requires the extraction of the narrative categories from the large corpus of narbs, and then identifying the connection between the categories to see the story told by the narbs. This process begins with the machine reading of the narbs to help the researcher narrow down the narbs into a manageable number of narrative categories. This process can be done by many different computer programs with varying degrees of sophistication depending on the amount of resources available to the researchers. For instance, large supercomputers such as the machine called “Watson” developed by International Business Machines (IBM) can do very complex analysis of natural human language as demonstrated in the machine winning a game of Jeopardy against human players (Markoff, 2011). Ultimately the goal is the “funneling” of the numerous narbs into a manageable number of “categories.”

The funneling is a tiered process where the narbs are analyzed by the machine to create a set of concepts that are extracted from the narbs. The number of concepts could still be quite large, for instance thousands of narbs could yield hundreds of concepts. Unfortunately, narratives cannot be built with hundreds of concepts with each concept acting as a narrative category. It is next necessary to parse the concepts into a suitable number of narrative categories that become the building block of the eventual narrative. This process is an iterative process where different concepts are collapsed into a set of coherent narrative categories. The notion of coherence is important to note since it connects with a key concept in the development of the narrative paradigm as proposed by Fisher. The idea of coherence examines the chances that the story makes logical sense and whether it “hangs together” with all its elements connected to each other. For instance, concepts represented by terms such as “good,” “great” or “excellent” can be collapsed into a single narrative category such as “positive affect.” The categories themselves are also built with the notions of narrative structure in mind. As suggested earlier in this essay, narrative analysts look for specific narrative categories to analyze a story. For instance, Barthe offers the various narrative codes that one can seek in a narrative, Propp offers several narrative units that can be found in a story. While these strategies are useful, and often applied to the analysis of narratives, they can also be used to create specific narrative categories that mimic the codes and units used in the analysis of narratives. This is precisely the method used in creating the narrative categories where the coherent concepts are collapsed into narrative categories that represent the different form of units and codes of a narrative.

Once the categories are produced it is then possible to analyze the categories – which now represent the large volume of narbs originally collected – to see the connection between the categories. In the tradition of syntactic analysis of narratives, where one of the objectives is to seek the connection between different narrative

categories, a correlation can be found in the narrative categories. The strength and direction of the correlation offers a sense of the connection between the categories, and a story, based on the numerous narbs, can now be formed by considering what connections are contained in the utterances of the numerous voices that make up the narbs. In the next section I offer a set of examples of the way in which these stories can be constructed from narbs available in the public domain. In each case the data was collected in different ways and from different sources. The goal was, however, similar – to process the data using the technique used above, and then creating a visual representation of the data, along with a short narrative, to be made available on a public Web site called the “TheMediaWatch.com” which was developed for the specific purpose of the popularization and dissemination of the narrative analysis of narbs across many different contexts.

The visualization is primarily in the form of a narrative map. As stated on the Web site, a narrative map is:

Narrative maps are produced from analysis of narbs, where the maps are made up of specific nodes and connectors. The nodes represent attitudes, concepts, behaviors and different issues that people are talking about in their narbs. For instance a common node is “positive opinion” which could be made up of positively affected terms such as “like,” “love,” “good,” etc. Similarly, another node could be “immigration” referring to the issue. The map connects nodes together to indicate how strongly two nodes are related to each other. For instance, a dark line between two nodes would show a strong relationship between the nodes, suggesting people are talking about two things simultaneously, almost “in the same breath!”

It is important to note that the relative placement of the specific nodes that represent the narrative categories obtained from the narbs is of no consequence to the narrative. What matters

most is the visible *size* of the node – a larger circle represents that the narrative category appeared more frequently than others – and the *thickness* of the line connecting nodes where a dark and thicker line represents larger number of narbs that included the narrative categories connected by the line. All the examples used in this essay are drawn directly from the Web site, which also acknowledges the various contributors to the different narratives described here.

The Ebola Virus

The first example deals with the type of narbs where the word length of the narb is unrestricted and the narbs appear on the Facebook digital network. Since the March of 2014, there was a World-wide panic related to the spread of the virus in some countries in Western Africa. There was a significant amount of discussion within popular culture about the implications and threats posed by the virus as a global phenomenon. As such, it also generated a large amount of narbs in various digital spaces. For the analysis that was presented on the Web site narbs were obtained in response to the information about the Ebola virus that was presented by the World Health Organization (WHO) through their presence on the Facebook digital space. The comments were collected in the winter of 2014 as a build up to the declaration by the WHO that the spread of the virus would be contained in the December of 2014. The narbs analyzed here represented the comments made on the Facebook “page” of the WHO.

The analysis of the narbs was conducted exactly in the manner described earlier and it was possible to identify several narrative categories from the narbs. A total of 800 narbs were obtained resulting in the narrative map presented here and on our Web site (see Figure 1).

As the narrative map demonstrates, there were several relevant narrative categories that was already in the public sphere as points of discussion such as “mosquitoes” and the general notion of “disease.” This narrative map offered the oppor-

Figure 1.

tunity to produce a narrative that was reported on the Web site as shown in Figure 2.

This combination of the map and the narrative offered a visitor to the Web site a concise picture of the narrative contained in the narbs that were obtained from the comments available at a digital network site such as Facebook. The next example uses narbs created as micro-blogs by users in the digital space created by Tweets.

The Indian Elections of 2014

The second example uses narbs of limited word length by obtaining tweets related to specific authors on the Tweeter digital network. The object of analysis were the tweets of the journalists collected over nearly twelve months leading up

to the elections and the tweets of the followers of the journalists over the same time period. The Big Data in this case was made up of a large number of people as well as a long period of time. Such Big Data eventually allow for longitudinal analysis as well as the analysis segregated by specific time periods. There were several different points where the analysis was visualized and distributed on the Web site. This example shows one such presentation that happened closer to the final moment of voting in May 2014 (see Figure 3).

This is a more complex map because of the many different issues related to the elections, and the diversity of narrative categories that were extracted from the narbs. This complexity is also related to the fact that this map offers an analysis of a much larger volume of data compared to the

Figure 2.

Figure 3.

previous example. The narrative that emerged from the data was also more complicated given the numerous elements that made up the narrative

One of the things to note about the narrative shown in Figure 4 is the fact that the narrative here is extracted not only from the narrative map, but the narrative also refers to specific computations of the percentages of different combination of narbs. The numeric analysis often adds to the value of the narrative, especially when the narrative might be used for specific policy decisions as demonstrated in the last example.

Hospice and Death

The Hospice Project used the third category of narbs where the narbs were solicited from respondents to a questionnaire that was distributed digitally. The respondents voluntarily answered “open-ended” questions about various elements of the medical system called “Hospice” which, in America, is often associated with “end of life” care and a general sense of “death.” The goal of this project was to discover what the respondents in the community thought about the connection

Figure 4.

Figure 5.

between the notion of death, and the idea of the Hospice (see Figure 5).

The map offered a glimpse into the opinions of the respondents expressed in the narbs that resulted in narrative categories that were quite unique, especially in the positive connection between the notion of death and Hospice, which ran counter to existing information. As a result the narrative was also provocative, resulting in some specific recommendations that were made to the Hospice and presented at the national conference (see Figure 6).

Indeed, the Hospice developed a new set of messages based on the narrative that was extracted from the narbs.

FUTURE RESEARCH DIRECTIONS

The argument presented here first suggests that it is possible to parse the overarching term – Big Data – in manageable sub-parts and each of these sub-parts offer different opportunities and challenges. Thus, the comments from the WHO presence on Facebook, the Tweets related to the elections in India and the self-response obtained through the distribution of a questionnaire all represent different aspects of Big Data and each can be obtained within the public sphere using means of data collection that are not extremely challenging as long as there is a clear sense of what kind of Big Data is being sought.

Figure 6.

The examples also addresses a second aspect of Big Data – the analysis of the material can be meaningful when there is a specific theoretical framework that informs the analysis. As long as there is reliance on a theory – in this case I use the narrative paradigm and the theory of narbs – it is possible to corral large amounts of information to answer specific research questions. The large volume of data is extremely seductive and it is often possible to continue to “drill” deeper into the structured aspect of Big Data trying to find connections and relationships without a specific conceptual framework driving the analysis. These examples illustrate the importance of theory in this process.

Finally, the examples also illustrate that once a theoretical approach is adopted it is possible to interpret the findings, such as the narrative maps, into coherent information that can be visualized and circulated in an understandable manner. Groups such as Infographics have been doing this with numeric data for some time, offering simple and attractive graphical representations of large amounts of data making it meaningful to most observers. It is far more difficult to do that with large amounts of discursive data which makes up the unstructured Big Data. This is the reason why different apparatuses of popular culture, for instance the mass media tools, focus on single narbs, such as a single Tweet, to make sweeping generalizations because capturing the essence of millions of narbs becomes far more difficult without a theoretical basis to support the finding. Here the collection of narbs is presented through the mechanisms of a narrative map and a simple narrative. These narratives could become much more powerful in impact than relying on specific small set of narbs to create a whole “news story.” The framework and the analysis offered could offer much more robust narratives.

CONCLUSION

In closing the role of www.themediawatch.com is to offer a way to grapple with the emerging volume of Big Data. It is likely that popular awareness and appreciation of the importance of Big data can be boosted as more of the findings can be presented on outlets like this Web site. These three examples are offered to demonstrate several aspects of the discussions related to the notion of Big Data in academia and popular culture in the late 2010s. The term has taken on a mythological power as it is used within many different circles (Daly, 2013). However, when specific applications of the term are sought within academia or popular culture, one is either faced with complex mathematics along with sophisticated computational discourse which remain inaccessible to many, making Big Data a mysterious construct whose utility is shrouded in incomprehensible language (see, e.g., Diebold, 2003; Lohr, 2013; Mayer-Schonberger and Cukier, 2013; Tien, 2013). On the other hand, sometimes in the regime of the popular, Big Data is presented as the answer to all future decision making processes as well the “bogey man” that will eventually snatch away all elements of personal privacy and drive us to the dystopian future as pictured by George Orwell in his novel, *1984*.

KEY TERMS AND DEFINITIONS

Big Data: This is personalized data that is coming from people who are actively and voluntarily contributing to the compilation of these data sets. Much of the attention on big data has focused on the two key components: (1) gathering the large amounts of data and (2) quantitatively analyzing the data to obtain both personal-individualized information as well as information about different groups of people.

Data Visualization: The process of translating complex data and data interpretations into visual graphs and figures that capture the complexity in easy to understand and easy to communicate images.

Narb: As stated by the World Future Society on their Web site (<http://www.wfs.org/futurist/january-february-2013-vol-47-no-1/tomorrow-brief/wordbuzz-narbs>): “Narrative bits, or “narbs,” refer to small bits of information in the digital universe that, when collected, tell an otherwise untold story. The term is credited to Wake Forest University communication professor Ananda Mitra, who believes that narbs offer a way to turn massive amounts of social communication into a tool for predicting behavior and reactions.”

Narrative Map: Narrative maps are produced from analysis of narbs, where the maps are made up of specific nodes and connectors. The nodes represent attitudes, concepts, behaviors and dif-

ferent issues that people are talking about in their narbs. For instance, a common node is “positive opinion” which could be made up of positively affected terms such as “like,” “love,” “good,” etc. Similarly, another node could be “immigration” referring to the issue. The map connects nodes

together to indicate how strongly two nodes are related to each other. For instance, a dark line between two nodes would show a strong relationship between the nodes, suggesting people are talking about two things simultaneously, almost “in the same breath!”

B

Mining Big Data and Streams

Hoda Ahmed Abdelhafez

Suez Canal University, Egypt

INTRODUCTION

Mining big data is getting lot of attention currently because the businesses need more complex information in order to increase their revenue and gain competitive advantage. the growing of the telecommunication data traffic according to Cisco annual forecasting will reach 8.6 zettabytes by the end of 2018 up from 3.1 zettabytes per year in 2013 (Cisco analysis, 2014). Therefore, mining the huge amount of data as well as mining real-time data needs to be done by new data mining techniques/approaches. Big Data is a new term used to identify the datasets that are of large size and have grater complexity (Bifet, 2013). Data mining (DM) is the process of searching large volumes of data automatically for patterns such as association rules (Gupta et al., 2014). Big data mining is defined as the capability of extracting valuable information from large datasets or streams of data that due to its characteristics it is not possible before to do it (Fan & Bifet, 2013). This chapter will discuss the challenges of big data, new data mining techniques compared with traditional techniques and the main DM tools for handling very large datasets. Moreover, the chapter will focus on two industrial areas telecommunications and healthcare and lessons learned from them.

BACKGROUND

The data produced nowadays is estimated in the order of zettabytes, and it is growing around 40% every year. We need new algorithms, and new tools to deal with all of these data. Therefore,

the use of big data is becoming a crucial way for leading companies. For example, in healthcare, data pioneers are analyzing the health outcomes of pharmaceuticals when they were widely prescribed, and discovering benefits and risks that were not evident during necessarily more limited clinical trials (McGuire, 2012). We selected some significant articles that discussed challenges, techniques and tools for mining big data. Yadav et al. (2013) presented a review of several algorithms from 1994-2013 necessary for handling big data set. It gives an overview of architecture and algorithms used in large data sets, various tools that were developed for analyzing them as well as various security issues and trends. Bifet (2013) discussed data stream mining and how it offers many challenges and also many opportunities. Che et al. (2013) presented an overview of mining big data and its challenges include heterogeneity, scalability, speed, accuracy, trust, provenance and privacy. This paper also provides an overview of the platforms for processing and managing big data as well as platforms and libraries for mining big data. Jovic et al. (2014) discussed several data mining tools including RapidMiner, R, Weka, KNIME, Orange, and scikit-learn. Fan and Bifet (2013) presented big data challenges, applications of mining big data, Apache Hadoop and other open sources for big data mining and big graphic mining. Singh (2014) discussed machine learning techniques to capturing the value hidden in big data. He presented supervised learning using neural networks, Support Vector Machines (SVMs) and Naive Bayes classifiers, and also unsupervised learning using k-Means, hierarchical clustering and self-organizing maps.

CHALLENGES OF BIG DATA SYSTEMS

Big data has five key elements: Volume, Velocity, Variety, Veracity and value. These 5 V's are considered challenges of Big Data systems (Yin & Kaynak, 2015; Ishwarappa & Anuradha, 2015; Marr, 2015).

Volume refers to the huge amount of data. Many companies have large archived data in the form of logs but do not have the capacity to manipulate and analyze that data using traditional database technology. Now big data technology can help store and use these datasets in order to gain benefits from them.

Velocity represents the speed at which data generated and the speed at which data moves around. The speed at which credit card transactions is checked for fraudulent activities and the social media messages going to viral in seconds. Thus, big data technology can be used to analyze the data while it is being generated without putting it into databases.

Variety means different data types or format. Traditional database can store and process structured data that fit into tables such as financial data. Now 90% of data generated is in unstructured form and it cannot easily be put into relational databases such as photos, video sequences or social media updates. Big data technology can now harness various types of data like messages, photos, sensor data, and social media conversations and bring them together with more structured data.

Veracity refers to the trustworthiness of the data. The quality and accuracy of big data are less controllable because there will be dirty data. For instance, twitter posts with hash-tags, abbreviations, typos and colloquial speech. Big data analytics now allows us to work with these types of data. The volume, variety and velocity of data often make up for the lack of quality or accuracy.

Value refers to the ability to turn big data into value. Value is the most important aspects of big data because implement IT infrastructure systems are very costly to store big data and businesses are

going to require a return on investment. Big data can deliver value in almost any area of business or society such as improving healthcare and better understanding and serving customers.

There are other important challenges in big data management and analytics such as analytics architecture and hidden big data (Singh, 2014). Some key issues like accuracy and privacy are also very critical in mining big data (Che et al., 2013).

DATA MINING TECHNIQUES FOR LARGE SCALE DATA

The challenges in handling big data include capturing, storage, analysis, sharing, visualizing and more. In addition to connection and correlation of data which describes more about relationship among the data. Therefore mining big data needs new architecture, algorithms, techniques for its implementation. This section is focusing on the data mining techniques/methods that can be used for handling big data. These techniques/methods are classified classification, clustering, association rules, time series and data streams as follows:

Classification

One of the important classification techniques is decision tree. Decision tree learning is fast and accurate. Building Decision trees from large datasets requires long time for processing all the training instances and the available memory may be not sufficient for storing the whole training set. Implementation of traditional algorithms for building Decision trees becomes very time consuming. Therefore, many incremental algorithms are available such as BOAT (optimistic decision tree construction), ICE (implication counter examples) and VFDT (very fast decision tree) for handling large datasets (Franco-Arcega et al., 2013). The hybrid approach combining both decision tree and genetic algorithm are also used to create optimized decision tree in order to improve classification performance (Yadav et al., 2013). Another clas-

sification technique is Artificial Neural network (ANN). ANN is used for large data sets described the techniques of SOM (self-organizing feature map) network and LVQ (learning vector quantization networks). SOM reduces the dimensions of data through the use of self-organizing neural networks and it takes input in an unsupervised manner. The self-organizing map is a single layer feed forward network where the output syntaxes are arranged in low dimensional grid. LVQ uses supervised learning to categorize large data set into small sets in order to improve the overall computing time needed to process the large data set (Lu & Fahn, (2007).

Clustering

Clustering is a process of grouping objects with similar properties. The main clustering techniques for handling large data sets are Hierarchical clustering algorithms, K-means clustering algorithms, and Density Based Clustering (Vijayalakshmi & Renuka devi, 2012). Hierarchical clustering (HC) can be classified into two approaches agglomerative hierarchical clustering and divisive hierarchical clustering. In agglomerative approach, each data points are considered to be a separate cluster and the clusters are merged based on criteria. In divisive approach all data points are considered as a single cluster and they are splitted into number of clusters based on certain criteria. Two examples of hierarchical clustering algorithms are:

1. Clustering- Based SVM (support vector machine), which trains a very large datasets using the hierarchical micro clusters (Yu et al., 2003), and
2. Efficient hierarchical clustering using P-trees algorithm for handling multimedia-, stream- and spatial data for efficient data storage and access.

K-means clustering is another method of cluster analysis that aims to partition n observations into k clusters and each observation belongs to

the cluster with the nearest mean. The limitation is this method requiring the user to predefine K parameter for a clustering solution, which is often non-deterministic. To overcome this problem, parallel k/h -Means algorithm could use for clustering large distributed data sets; it is scalable and enlarges its field of application to clustering tasks. *Finally*, Density Based Clustering is another method identifying clusters in large high dimensional data set having different size and shape, and it is suitable for handling noise in dataset. DBSCAN and DENCLUE are examples for this algorithm as well as DESCRY a new algorithm to identify clusters in large high dimensional data set having different size and shape. DBSCAN is a density-based algorithm that treats clusters as dense regions of objects in the spatial space separated by regions of low density. DENCLUE is a highly efficient Density-based algorithm to deal with high dimensional datasets and it is faster than CLARANS (improved k -medoid method) and DBSCAN (Ding et al., 2015).

Association Rules

Association rules are used to discover facts that often occur together within a particular dataset. Many algorithms have been proposed in the past. For example, the Apriori algorithm is used for mining frequent itemsets for Boolean association rules. This algorithm is based on previous knowledge (a priori) of the sets of frequent data items. An item is considered frequent if its frequency of appearance in the database is higher than the minimum support threshold. The Apriori algorithm has big problems with large volume of Big Data. It does multiple scans of the whole database, thus the execution time increases in line with the number of transactions (Nedunchezian & Geethanandhini, 2016; Fernandez-Basso et al., 2016). Another algorithm is Eclat using bottom up approach to finds the itemsets from the dataset like depth first search. Eclat algorithm is very simple method to find the frequent item sets. It scans database only once. It is suitable for small datasets also it

requires less time for frequent pattern generation than apriori. Some new algorithms/methods are proposed for mining Big Data. BigFIM method is optimized to run on really large datasets. BigFIM, it is a hybrid method. It uses the Apriori algorithm to extract frequent itemsets of length k and later on it moves to Eclat when the projected databases fit in memory (Moens et al., 2013). Another new method is PARMA, it divides dataset into samples in order to give the better and fast results. PARMA is implemented using Map Reduce framework. It has two stages. In the first stage, N samples are created using first Map function and the samples are mined using first Reduce function. Second is the aggregation stage, all the results of samples are combined to get a whole set of frequent itemsets in a database (Riondato et al. 2012).

Time Series

Time series databases consist of sequence of events or values over repeated measurement of time. With the growing deployment of a large number of sensors and online data collection tools, the amount of time series data is increasing rapidly. Moreover, time series are a rich and important data source for detecting abnormal states, diagnosing performance issues such as finance, communication, automatic control, and online services, etc. (Mahajan et al., 2012).

Time Series Data Mining is a framework of analysis time series data for discovery and use of patterns as well as prediction of future values. Data in Time Series has lots of variations, therefore, both clustering and classification methods are used (Mahajan et al., 2012). Sampling techniques are adopted to reduce the size of time series dataset such as DENCLUE 2.0. It employs random sampling with different sample sizes to reduce the number of iterations for density attractor estimation. However, the sample size is chosen in an ad hoc manner in DENCLUE 2.0, and how to set proper sample size for arbitrary large-scale time series datasets is still difficult and unknown (Hinneburg and Gabriel, 2007). YADING, a

novel time series clustering algorithm is used to automatically cluster large-scale time series with fast performance and quality results. YADING consists of three steps: data reduction, clustering, and assignment. Data reduction reduces the dimensionality of the input time series instances (Ding et al., 2015).

Data Streams

Data stream means continuous flow of data; the size of the data is extremely large and potentially infinite. Examples of data stream include phone conversation, web searches and sensor data. Data stream mining is a process of extracting knowledge structure from continuous, rapid data records. There are two types of data Stream online streams and offline streams. Online data stream mining used in a number of real world applications such as fraud detection and network traffic monitoring; offline data stream mining is like generating report based on web log streams. Thus, increasing rate from such applications like sensor networks and call detail records need data stream real time analytics to manage data currently generated (Parikh & Tirkha, 2013). Mining data streams face great challenge in storage devices as well as the need for different techniques in order to extract patterns/knowledge (Trambadiya & Bhanodia, 2012).

There are many techniques for data stream classification; we will discuss decision tree algorithms for classifying data streams. These algorithms are the Hoeffding Tree, Very Fast Decision Tree method (VFDT) and Concept adaptive Very Fast Decision Tree method (CVFDT). Hoeffding tree provides incremental approach and scale different attributes better than tradition decision tree. It is capable of learning from massive data streams. Both Hoeffding Window Tree and Hoeffding Adaptive tree can cope with concept and distribution drift on data streams (Bifet & Gavalda, 2009). VFDT is based on Hoeffding tree algorithm. It use basic fundamental of a decision tree learning that is capable of learning from high speed data

streams in an incremental anytime fashion. The incremental approach in VFDT means where as a new example come it merged with old data. CVFDT is an extend VFDT to keep trees up to date with time variant data streams. It implements sliding window of various dataset to keep its model consistent. CVFDT continuous monitors the quality of new data and adjusts those that are no longer correct. Every time a new data arrives, the CVFDT incrementing counts for new data and decrementing counts for oldest data in the window (Trambadiya & Bhanodia, 2012, Hulten et al., 2001).

TOOLS FOR MINING BIG DATA

There are many data mining tools for handling large datasets. We will focus on the main open source tools that can handle big data. These tools are Mahout, RapidMiner, R, MOA, KNIME, SPMF, Orange, and SAMOA.

Apache Mahout is Scalable machine learning and data mining open source software based on Hadoop. It has implementations of a wide range of machine learning and data mining algorithms including clustering (such as k-means, fuzzy k-means and streaming k-means), classification (such as logistic regression and Naive Bayes), collaborative filtering (such as user based collaborative filtering and item based collaborative filtering) and frequent pattern mining. While Mahout's core algorithms are implemented on top Apache Hadoop using Map/reduce, it does not restrict contributions to Hadoop-based implementations. Contributions that run on non-Hadoop cluster or on a single node are also welcomed. (Apache Mahout, 2014).

RapidMiner is an open source and Java-based, general data mining tool currently in development by the company RapidMiner, Germany. The tool has become very popular in several recent years and has a large community support. RapidMiner offers an integrating environment with visually appealing and user-friendly GUI. Everything in

RapidMiner is focused on processes that may contain sub-processes. Processes contain operators in the form of visual components. Operators are implementations of data mining algorithms, data sources, and data sinks. RapidMiner provides data mining and machine learning procedures including: data loading and transformation, ETL (Extract, transform, load), data preprocessing and visualization, predictive analytics and statistical modeling, evaluation, and deployment. Although RapidMiner is quite powerful with its basic set of operators, it is the extensions that make it even more useful. Popular extensions include sets of operators for text mining, web mining, time series analysis, etc (Jovic et. al., 2014, RapidMiner Review, 2015).

R open source programming language designed for statistical computing and visualization. R is the successor of S, a statistical language originally developed by Bell Labs in 1970s. The source code of R is written in C++, Fortran, and in R itself. Interface to R is command line and use through scripting. Extension of R is implemented as an R library and provides a GUI to many of R's data analysis and modeling functions. From data mining user's perspective, R offers very fast implementations of many machine learning algorithms, comparable in number to RapidMiner. It has specific data types for handling big data, supports parallelization, web mining, data streams, graph mining, spatial mining, and many other advanced tasks (Jovic et al., 2014).

MOA (Massive On-Line Analysis) is open source software to perform data mining stream. MOA is related to WEKA, which is an award-winning open-source workbench containing implementations of a wide range of batch machine learning methods. It contains collection offline and online for both classification and clustering as well as tools for evaluation. In particular, for classification it implements boosting, bagging, and Hoeffding Trees, all with and without Naive Bayes classifiers at the leaves. For clustering, it implements StreamKM++, CluStream, ClusTree, Den-Stream, D-Stream and CobWeb. MOA is

written in Java so that the applications can be run on any platform with an appropriate Java virtual machine. MOA streams can be built using generators, reading ARFF files, joining several streams, or filtering streams. They allow for the simulation of a potentially infinite sequence of data. Examples of these generators are: Random Tree Generator, STAGGER Concepts Generator, SEA Concepts Generator, LED Generator, Waveform Generator and Function Generator (Bifet et al., 2010).

KNIME (Konstanz Information Miner) is a general purpose data mining tool based on the Eclipse platform. It is developed and maintained by the Swiss company KNIME.com AG. KNIME is an open-source, though commercial licenses exist for companies requiring professional technical support. The KNIME tool has building blocks called nodes, and than 1000 nodes are available through the core installation and various extensions. Nodes are organized in a hierarchy and can be searched by name within an intuitive interface. Each node performs a certain function, such as reading data, filtering, modeling, visualization. It is documented in detail and the nodes have input and output ports. Some node handle data model as classification trees. One of the greatest strengths of KNIME is the integration with WEKA and R. WEKA integration enables using almost all the functionality available in Weka as KNIME nodes, while R integration enables running R code as a step in the workflow, opening R views and learning models within R (Bifet, 2013; Jovic et al., 2014).

SPMF (Sequential Pattern Mining Framework) is an open-source data mining library implemented in Java. It is specialized in frequent pattern mining such as association rules and sequential patterns. SPMF offers implementations of more than 55 data mining algorithms. The source code can be integrated in other Java programs. Moreover, SPMF offers a command line interface and a simple graphical interface for quick testing. There are many general purpose open source data mining libraries such as Mahout and Knime that provide a wide range of data mining techniques. However, they offer a very limited set of algorithms for

frequent pattern mining. Knime and Mahout offer only a few popular pattern mining algorithms such as Apriori and GSP (Viger, 2014).

Orange is a Python-based tool for data mining and also an open source platform. It can be used either through Python scripting as a Python plugin, or through visual programming. Orange Canva offers the following functionalities grouped into nine categories: data operations, visualization, classification, regression, evaluation, unsupervised learning, association, visualization using QT (a cross platform development framework) and prototype implementations. Functionalities are visually represented by different widgets (such as read file, train SVM classifier etc). The visual programming environment of Orange uses graphical widgets that combine methods from the core library and associated modules to help users develop custom algorithms. The data mining algorithms of Orange are organized in hierarchical toolboxes, which make them easy to implement. Although, the downside of Orange is that the number of available widgets seems limited when compared to other tools (such as KNIME or RapidMiner), the coverage of standard data mining techniques is quite good (Jovic et al., 2014).

SAMOA (Scalable Advanced Massive Online Analysis) is an open source platform for mining big data streams and it is written in Java. Its aim is to satisfy the future needs for big data stream mining by combining the two approaches (streaming algorithms and distributed computing) in a single platform. It provides a collection of distributed streaming algorithms for data mining and machine learning tasks such as classification, clustering, and regression. For example, SAMOA includes a distributed version of CluStream, an algorithm for clustering evolving data streams. It also provides an API for algorithm developers that simplify implementing distributed streaming algorithms. It features a pluggable architecture that allows it to run on several distributed stream processing engines such as Storm, S4, and Samza (Morales & Bifet, 2015).

MINING BIG DATA IN TELECOMMUNICATIONS

Big data in telecommunication industry creates the need to analyze multiple data types including location data, social media (such as facebook and twitter), data from sensors and natural language text in order to provide insights that can enable them to increase revenues and reduce costs (Dam, 2013). Large volumes of data come from collecting millions of call details records per day, smartphones, tablets, personal computers, networks sensors and social media and the like. These data are in myriad formats and need to be analyzed in near real-time. Moreover, the volume of signaling data from smart phones, tablets and other devices that are application dependent has also increased significantly (informatica, 2012). The AT&T long distance data stream consists of approximately 300 million records per day from 100 million customers. Data in Time Series has lots of variations, as in telecom industry, some data sequences are long like billing data and each data item in a time series is a multidimensional vector. To overcome these difficulties two steps are followed: first, transform the data into equal-length vectors using a model based clustering method. Second, use standard classification method such as decision tree and/or SVM methods (Mahajan et al., 2012).

Fraud detection is important to the telecommunications industry because companies and suppliers of telecommunications services lose a significant proportion of their revenue as a result. Fraud in telecom can actually be viewed as fraud scenarios, which are related to the way the access to the network was acquired. Fraud detection focuses on the evaluation of different user profiles and their effect towards the proper discrimination between legitimate and fraudulent activity. The user daily profiles will be used as an input for the two algorithms K-means and the hierarchical clustering techniques called agglomerative clustering algorithm. The data of the basic profile vector for a telecommunications user are contained in the

Call Detail Record (CDR) of any Private Branch Exchange (PBX) or any VoIP switch. Mainly a CDR contains at least data such as the caller ID, the chargeable duration of the call, the date and the time of the call, etc. The experiments are based on real data extracted from a database that holds the CDR for a period of eight years from an organization's PBX. According to the organization's charging policy, only international and mobile destinations are charged. The k -means algorithm is used to partition the input space in two distinct groups. If the legitimate and the fraudulent behavior cases are sufficiently different from each other, then the k -means algorithm will provide two distinct clusters of data. If this is not the case, then the same input data will be fed into the agglomerative clustering algorithm to check whether there is an output with distinct cases separation (Hilas et al., 2015).

Churn is the movement of customers from one mobile network operator to another. Telecommunication faces an increasing churn rate compared with other industries. Increasing churn rate causes losing a high valued client means a loss of future incomes. Therefore, customer retention has become very important for marketing campaigns. It is more profitable for mobile telecom operators to invest in those customers that already have an experience with the service by renewing their trust, rather than trying to attract new customers characterized by a higher churn rate. A hybrid learning model built on data mining techniques is implemented to explain the churn behavior with more accuracy than single methods; and that in some extend the reason of churn can be revealed, as well as explaining the gap between the decision to churn and the deactivation time. This hybrid model is built using WEKA; it includes Logistic Regression (LR) in parallel with Voted Perception (VP) for classification, and combined with clustering. A real world dataset from an Asian mobile operator are used to evaluate the performance of the model. Two methods are combined in parallel to reinforce the classification. LR is used as major classifier and VP reinforce the prediction. The

Data preprocessing step transforms the selected input data in an appropriate format for analysis in WEKA knowledge flow. The evaluation of the model shows that its accuracy is higher than when using single model. The investigated case shows that four months period where enough for a churn to show his dissatisfaction before the deactivation; this depending on the Tenure and the data collection periodicity (Olle & Cai, 2014). Another framework for predicting customer behavior based on application hybrid learning approaches for churn prediction in mobile network. This framework used hybrid model including decision tree induction C4.5 and genetic algorithm to give a pragmatic churner model. The hybrid model is used for prediction of various user defined groupings based on usage time, location and their underlying social network (Yeshwanth, Raj, & Saravanan, 2011).

Transactional data streams are a challenging domain in which to apply data mining ideas because of a huge volume of simple records and a dynamic continuous flow of data. AT&T has approximately 5 million call detail records (CDRs) per day relating to international telecommunications traffic from 12 million accounts. A stream of CDRs associated with AT&T's wireless communications services includes approximately 80 million records per day from 15 million accounts. AT&T has developed signature-based methods for fraud and intrusion detection. Anomaly detection via signatures is used by AT&T for telecommunications fraud detection involving international calling. It uses anomaly detection to measure the unusualness of a new call specific to a particular account (or to a fraudster), and it uses a profile-based approach to characterize this unusualness as fraud. Finally, AT&T methodology can be fooled by fraud that is slowly introduced into an account's traffic. The good news is that this type of fraud will be caught by a secondary and highly distributed detection mechanism—namely the customers themselves—as itemized bills are sent out every month for payment (Cortes & Pregubon, 2001).

MINING BIG DATA IN HEALTHCARE

Data mining in healthcare industry is an important field for providing prognosis and a deeper understanding of medical data. Applications of data mining in healthcare include analysis of health care centers for better health policy-making and prevention of hospital errors as well as early detection of diseases. Health care industry today generates huge amounts of complex clinical data about patients and other hospital resources. Data mining techniques are used to analyze these rich collections of data from different perspectives and extracting useful information. (Mariamma et al., 2014; Venkatalakshmi & Shivsankar, 2014).

Mining data streams is required for real-time medical prediction and classification in clinical support systems. One of the main algorithms in clinical support system is decision tree for handling continuous rapid data streams. Very Fast Decision Tree (VFDT) an advanced decision tree algorithm that can handle large amounts of continuous data (data streams). The proposed system implements VFDT with the capability using pointers to allow the decision tree to remember the mapping relationship between leaf nodes and the history records. For each leaf nodes, it can be looked as a class label and it indicates a certain kind of medical situation (illness). Each leaf node has one or several pointers. These pointers are added by the learning algorithm in the training process. Each pointer has a unique value and each pointer represents a unique medical record. This way can save the need of the offline clustering process (Zhang et al., 2012).

Breast cancer is one of the major causes of death in women; therefore, the early detection and accurate diagnosis of this disease can ensure a long survival of the patients. Breast cancer research using data mining techniques has been one of the important topics in medical science during the recent years. Early diagnosis requires an accurate and reliable diagnosis procedure that allows physicians to distinguish benign breast tumors

from malignant ones. An experiment conducted on the Wisconsin Breast Cancer Dataset (WBCD) taken from UCI Repository of Machine Learning Databases. The dataset contains 699 instances taken from needle aspirates from patients' breasts, of which 458 cases belong to benign class and the remaining 241 cases belong to malignant. A hybrid model of decision tree based support vector machine (SVM) diagnostic system is implemented using Weka tool with Java platform for breast cancer diagnosis. Classification had two main phases, Training and Testing phases. The input parameters for SVM were optimized using decision tree algorithm. The SVM algorithm was used to classify breast cancer patients into one of two classes (Benign/Malignant). The advantage of decision tree-SVM method is that it provides higher accuracy than other compared algorithms (Sivakami, 2015).

Heart disease is a major health problem and it affects a large number of people. Cardiovascular Disease (CVD) is one such threat. To develop diagnosis and prediction system for heart diseases based on predictive mining, a number of experiments has been conducted to compare the performance of various predictive data mining techniques including Decision tree and Naïve Bayes algorithms. The dataset for this proposed work includes a 13 attribute structured clinical database from UCI Machine Learning Repository. This dataset consists of attributes and values. Decision tree and Naïve Bayes have been applied for the diagnosis of heart disease. The prediction of heart disease is executed with the help of a tool known as Weka. The results of this tool are the accuracy of how many patients are having the heart disease with in a particular time. In order to improve the efficiency and accuracy an optimization process is carried out using genetic algorithm. The genetic algorithm is being implemented with the help of Matlab. The optimized attributes are fed into Weka tool for the prediction purpose. The results show that the optimization technique is the best method for improving the prediction of heart disease. Benefit of using genetic algorithm

is the prediction of heart disease can be done in a short time with the help of reduced dataset. (Venkatalakshmi & Shivsankar, 2014).

FUTURE TRENDS

The next research will focus more on different big data mining tools and illustrate strengths and weaknesses through making comparison among them. The next research will also discuss big data mining in other industrial areas such as retailing and banking and finance.

CONCLUSION

Mining big data has a lot of challenges because of the scale, complexity and heterogeneous of datasets. Thus the new techniques and tools for mining large dataset have been tried to handle these challenges. This chapter discussed the data mining techniques/ algorithms like advanced decision tree and hierarchical clustering algorithms that are able of handling massive datasets. Some of open source tools for mining big data are also discussed like WEKA, MOA and Apache Mahout and how these tools help telecom and healthcare industries to extract useful information. Mining big data in telecommunication and healthcare industries represents big opportunities in these industries. In healthcare, mining massive amounts of complex clinical data using advanced algorithms can provide a deeper understanding of medical data and help saving patients lives. Telecommunication industry also deals with millions of call details records per day as well as data from smartphones, tablets, personal computers, networks sensors and social media and the like. Mining these data can help telecom detecting fraudulent and improving customer retention to reduce churn rate as well as improving the customer experience. So we can conclude that mining big data can help the companies to understand their customers, driving their businesses forwards and increasing their revenue streams.

KEY TERMS AND DEFINITIONS

Big Data: The datasets that are of large size and have a greater complexity.

Data Mining: The process of searching large volumes of data automatically for patterns.

Data Stream: A continuous flow of data.

Mining Data Stream: The ability to extract valuable information from large data streams.

Category B

Bioinformatics

Bioinformatics

INTRODUCTION

Over the past 30 years, bioinformatics has emerged as new discipline at the interface of molecular bioscience with mathematics, computer science and information technology. Bioinformatics is driven by data arising from high-throughput technologies in molecular bioscience including DNA and genome sequencing, gene expression analysis, protein and RNA structure characterisation, and bio-imaging. To enable biological discovery, bioinformatics draws on and extends technologies for data capture, management, integration and mining, computing, and communication technology including the Internet. The rise of genomics, from the first bacterial and model-organism projects to the Human Genome Projects and the thousands of genome projects that have followed, has been a key driver for bioinformatics, and in turn has enabled these projects to be completed and their results applied. Genomics, however, was never an end unto itself, but rather was intended to enable the understanding of complex biological systems. Bioinformatics continues to evolve in support of its constituent domains and, increasingly, their integration into genome-scale molecular systems biology.

This article presents bioinformatics first from the perspective of computer science and IT, then from the perspective of bioscience. In practice these perspectives often merge, making bioinformatics a rich, vibrant area of multidisciplinary research and application.

BACKGROUND

The term *bioinformatics* was introduced in 1970 in reference to the study of informatic processes in biological systems (Hogeweg, 2011). In this original usage, *bioinformatics* encompassed “how living systems gather, process, store and use information” (Nurse, 2008). Never widely adopted, this usage was superseded in the late 1980s when bioinformatics, as presently understood, emerged as a new field at the interface of molecular bioscience with computer science and information technology (Dickson, 1987). Today bioinformatics builds on mathematics, statistics and algorithmics, and finds applications across the biosciences particularly in genomics, proteomics, structural biology and molecular systems biology. Biology is increasingly an information science, with bioinformatics a key enabling technology.

Other disciplines have developed at the bioscience - computer science - IT interface, and there is little consensus on where boundaries should be drawn among them. Bioinformatics is sometimes said to focus on the development and application of methods and software tools to acquire, manage, analyse and/or visualise biological data, whereas *computational biology* refers more to the application of these methods and tools to theoretical or applied biological questions (Huerta *et al.*, 2000). *Biomathematics* or *mathematical biology* involves the development or use of mathematical modeling or simulation, while *biostatistics* emphasises experimental design and statistical analysis. *Mo-*

lecular systems biology focuses on the inference or analysis of networks of genes, proteins and/or other cellular molecules, while *synthetic biology* applies these technologies to design and engineer new biological functions or organisms.

BIOINFORMATICS FROM THE PERSPECTIVE OF COMPUTER SCIENCE AND INFORMATION TECHNOLOGY

One way of exploring the interface between molecular bioscience and IT is to track experimental data from their generation, capture and retrieval, through their aggregation and dissemination *via* international data services, to their subsequent analysis. Here I deconstruct data analysis into data models, algorithms, analytical methods and software, workflows and visualisation. This trajectory is common to scientific data, although bioinformatics is notable for its culture of open data, well-established data formats and standards, and data reuse facilitated by large international repositories with associated data services.

Data Generation, Storage and Retrieval

Instruments and experiments generate diverse data types in molecular bioscience. Capturing these primary data and the associated metadata, and managing their storage and retrieval, are primary activities in bioinformatics. The quantities of data generated by DNA-sequencing platforms, in particular, are such that raw data are no longer archived; rather, bioinformatic methods are used to assess quality and extract summaries. Data formats are specific to experimental technologies and, to some extent, instrument manufacturers. In some areas of molecular bioscience, standards have been developed to ensure that data can be interpreted unambiguously and, in principle, the experiment can be reproduced. For example, the MIAME (Minimum Information About a Mi-

croarray Experiment) standard (Brazma *et al.*, 2001) specifies how experimental design, laboratory protocols, biological samples, microarray platforms, and raw and processed data must be described, and recommends the use of certain data formats and ontologies. The MIBBI project promotes the coherence of minimum-standards checklists across nearly 40 areas of bioscience and biomedicine (Taylor *et al.*, 2008).

Public Data Resources

Newly generated biomolecular data (*e.g.* DNA and protein sequences, protein structures, gene-expression data) are submitted to public data repositories, where they are assigned unique persistent identifiers; all major bioscience journals require new data to be so identified. The main international collection centres are the US National Centre for Biotechnology Information (NCBI), the EMBL European Bioinformatics Institute (EBI), and the DNA Data Bank of Japan (DDBJ). Individually and in collaboration with each other, these centres carry out further quality control on incoming data, conduct research in bioinformatics, promote best practice in bioscience data management and analysis, and provide comprehensive online data services (*e.g.* search, retrieval, integrative analyses over multiple data sources, and links to journal articles and patents) which are cost-free at the “point of use” for the international research community. Other public data resources serve specific areas of molecular bioscience, *e.g.* protein structure. Increasingly, the largest projects in molecular bioscience maintain their own public data resources, *e.g.* The Cancer Genome Atlas and the International Cancer Genome Consortium. Both large and small data sources are reviewed in the annual Database issue of the journal *Nucleic Acids Research*.

Data Formats and Models

The need for data integration and re-use has driven the development of standard data presentation

formats, notably the FASTA format (Lipman & Pearson, 1985). However, no single data model has been universally adopted across all bioinformatics applications. Many public data services provide flat (ascii) files, but relational (MySQL), semantic (RDF), Web Services and hybrid approaches are also in use. Third-party tools such as SRS or BioMart are often used to integrate and index multiple related collections for combined use. With public data now in the tens of petabytes and growing rapidly, bioinformatics has entered the era of Big Data.

Algorithms and Computation

The molecular biosciences offer diverse and difficult analytical challenges, against which a wide range of algorithmic approaches are deployed. Gene and protein sequences map naturally to strings, regulatory signals to motifs, phylogenies to trees, lateral genetic transfer to edits on trees, genetic regulatory networks and protein interactions to networks, and so on. Thus operations in bioinformatics can often be recast as known or new problems in *e.g.* string matching, motif discovery, classification or graph theory. Many problems mapped in this way are NP-hard, *e.g.* maximum clique, vertex cover and Steiner tree (Karp, 1972), or are suspected of being so. Increasingly, however, many are fixed-parameter tractable, allowing high-quality solutions even on very large bioscience data. Heuristics are important in bioinformatics as well: the sequence alignment problem drove the early development of dynamic programming, phylogenetics is an important application domain for Markov chain Monte Carlo in conjunction with Bayesian approaches, and problems in gene regulation, protein localisation and biomolecular networks continue to provide challenges for machine learning. Even so, key problems in bioinformatics continue to pose algorithmic and computational challenges for large data, requiring computational infrastructure with large shared memory and/or high-capacity input/output.

Methods and Software

Innumerable bioinformatic methods and software exist. Many are developed for highly specific applications, and quickly fall out of use or are superseded. Stand-alone tools, available by download from websites, remain popular; other tools are available *via* public servers or webtools, or integrated into online data services. Coordinated sets of tools that share input/output formats and a common user interface are popular in some application areas, *e.g.* DNA sequence analysis (DNASTAR, Sequencher), motif discovery (MEME Suite) and phylogenetics (PAUP*, PHYLIP). The great majority of bioinformatic tools arise from academic research, with the attendant issues of stability, support and sustainability. Although bioinformatics is characterised by a robust open-source ethic and active developer/user communities exist around many toolsets, commercial software is important in some areas, notably structural biology, proteomics and bio-image informatics. Notices of new methods and software may appear in academic journals (*e.g.* the Application Notes section of *Bioinformatics*; the annual Web Server issue of *Nucleic Acids Research*).

Bioinformatic Workflows

An important class of tools supports the composition and execution of bioinformatic *workflows* or “pipelines”, *i.e.* linked series of data-manipulation and analytical steps. For example, software modules that retrieve and reformat sequences, align multiple sequences, and infer trees can be linked to form a phylogenetic workflow. Popular workflow-management frameworks in bioinformatics include BioConductor/R, Galaxy, GenePattern, GMOD, SRS and Taverna. E-research middleware that links data sources, analytical and visualisation tools, computational resources and storage are gaining popularity particularly for large-scale projects.

Data Visualisation

Visualisation of large bioscience data is likewise an important theme in bioinformatics. Challenges include the visual representation of very large, complex, multi-scale data; integration of visualisation with data mining and analysis; integrated display of different data types (*e.g.* pathways and gene-expression levels); standards; and augmented computer interaction (O'Donoghue *et al.*, 2010). Genome browsers (*e.g.* the ENSEMBL, IGV and UCSC Genome browsers) allow simultaneous display of one or more genome sequences together with additional experimental data (*e.g.* expression levels) and computationally based annotation. Stand-alone visualisation tools remain popular for defined tasks, *e.g.* visualisation of molecular structures (PyMol) and display of phylogenetic trees (TreeView).

BIOINFORMATICS FROM THE PERSPECTIVE OF BIOSCIENCE

Comprising the other side of the bio – IT interface are the multiple fields of modern molecular bioscience, arranged here in reference to the primary direction of information flow in biological systems, from DNA (genomics) to RNA (transcriptomics) to protein (proteomics). To a first approximation, DNA/genome bioinformatics focuses on the primary (linear) sequence, whereas protein informatics is equally or more concerned with three-dimensional folded structure. There is increasing appreciation that biological information flow is not unidirectional; the analysis of biomolecular networks and systems is one of the fastest-growing areas of today's bioinformatics.

Individual Molecular Sequences

DNA, RNA and protein sequences represent the largest application area of bioinformatics. Important problems in *sequence bioinformatics* include quality control and management of se-

quence data; assembly of full-length sequences; discovery and annotation of features (*e.g.* genes, regulatory signals); sequence comparison in functional and evolutionary contexts; and retrieval of similar sequences from databases. Some of the earliest bioinformatic algorithms and software were designed to manage and analyse individual sequences.

Genome Informatics

With progress in automated technologies, it is becoming commonplace to sequence the genetic material of an individual – the coding regions only (*exome sequencing*), or *whole-genome sequencing*. Many earlier methods have been repurposed, and new approaches developed, to assemble, annotate and analyse plant and animal genomes, which are typically 10^8 - 10^{11} basepairs in size and replete with low-complexity regions and repetitive elements. In *metagenomics*, these methods are applied to study DNA extracted directly from environmental samples, without prior isolation of individual species. Continuing innovation in sequencing technologies, including non-hierarchical (“shotgun”) strategies, short-read and single-molecule sequencing, and new types of data encoding, has been made possible by innovative bioinformatics.

Feature Discovery and Annotation

For a sequence to be useful in biological investigation, features represented therein must be discovered and annotated. Early discovery of features involved painstaking laboratory work; today, bioinformatic methods that draw on the body of experimental knowledge are the mainstay of feature annotation. Some features (*e.g.* transcriptional start and stop signals for bacterial genes) are conservative and can be found efficiently by similarity matching and/or rule-based inference, whereas others (*e.g.* transcription factor binding sites) are based on motifs of variable position and low information content, and can be discovered

(if at all) only by statistically based approaches including neural networks, hidden Markov models, support vector machines or other machine-learning approaches (Libbrecht & Noble, 2015). The MEME Suite (Bailey *et al.*, 2015) provides important programs for motif discovery and analysis. The annotation process is well-suited to a workflow-based approach.

Sequence Comparison

Many operations in bioinformatics involve the statistical comparison of two or more sequences. Historically, these problems introduced into bioinformatics important concepts from computer science including dynamic programming, hashing, and suffix trees. Comparison problems can be classified as pairwise, one-*versus*-many (*e.g.* finding best matches in a database), and many-*versus*-many (*e.g.* multiple sequence alignment). The heuristic Basic Local Alignment Search Tool (BLAST) is by far the most widely used bioinformatic algorithm for database searching (Altschul *et al.*, 1990); variants are available *e.g.* to match a nucleotide sequence against a nucleotide database, a protein against a protein database or a nucleotide sequence against a protein database, or preferentially to recover weak matches (more distantly related sequences). Software for multiple sequence alignment includes Clustal, MUSCLE, PRANK and T-Coffee, while bacterial genomes can be aligned with Mauve.

Phylogenetics

Although originally developed as subfields within evolutionary biology, *molecular phylogenetics* and its genome-scale counterpart, *phylogenomics*, are widely accorded a place in bioinformatics conferences, journals and texts. Important operations include database matching, clustering, multiple sequence alignment, and the inference and comparison of phylogenetic trees and networks. The main algorithmic frameworks for tree inference include distance (*e.g.* neighbour-joining),

parsimony, maximum likelihood and Bayesian inference, the latter using Markov chain Monte Carlo (MCMC) to estimate posterior distributions of model parameters. Important software includes the PHYLIP package, PAUP*, RaxML, BEAST and MrBayes (Yang & Rannala, 2012). As multiple sequence alignment and most methods of tree inference scale poorly with data size, heuristics are widely employed and alternatives that do not require multiple sequence alignment are being actively explored (Chan *et al.*, 2014). TreeBASE and the Ribosomal Database Project (RDP) are important repositories of phylogenetic models and data.

Gene Expression

The development of bioinformatic methods for analysis of gene expression has been driven by technology: the introduction of spotted arrays in the 1980s, microarrays of increasingly high density since 1995, and more recently sequence-based transcriptomics. Operations in *expression bioinformatics* include experimental design, data capture and management, normalisation (statistical correction for variation arising from the array platform rather than from the biological sample), analysis of differential expression (*e.g.* under different experimental conditions), clustering, classification and functional interpretation. Specialised methods continue to be developed for the study of alternative splicing, other types of transcriptional variation, and regulatory RNAs. Both commercial (GeneSpring) and free (LIMMA; programs in BioConductor/R and GenePattern) software is widely used to analyse expression data.

Epigenetics

Epigenetics refers to heritable states in gene expression or phenotype caused by mechanisms other than changes to the sequence of genomic DNA. Large-scale epigenetic data have recently begun to appear with the advent of technologies that probe the methylation status of DNA,

chemical modifications of histones, structural conformation of the chromatin and occupancy of control sites in specific cell types and/or under specified conditions. Bioinformatic operations in epigenetics are not unlike those in genome analysis and annotation, with emphasis on statistically based approaches including machine learning. ENCODE (Encyclopaedia of DNA Coding Elements) is a very large consortium project whose aim is to assess the activity and function of the entire genomic DNA, not only protein-coding genes (Ecker *et al.*, 2012).

Structural Bioinformatics

Structural bioinformatics focuses on the computational analysis of the three-dimensional structures of biomolecules, especially proteins and RNAs. Important activities include the description or prediction of protein structures, surfaces, dynamics and interactions with other molecules including antibodies and drugs (Gu & Bourne, 2009). Important software packages include Amber, Gaussian, GROMACS and NAMD. The Critical Assessment of Techniques for Protein Structure Prediction (CASP) is a biennial community-wide competitive evaluation of methods and software, while Folding@Home is a distributed computing project for protein folding and computational drug design. For RNAs, recurrent themes include the prediction of folded structure and target specificity. Software includes the Vienna package, UNAFold, miRanda, PicTar and TargetScan. Databases include PDB, Swiss-Prot, UniProt (proteins) and Rfam (RNA).

Systems Bioinformatics

Systems bioinformatics aims to understand cells or organisms as integrated molecular systems. Typical operations include management and integration of multiple types of genome-scale data; inference of biomolecular interactions, pathways (*e.g.* of

biosynthesis or metabolism) or networks (*e.g.* of genetic regulation or protein-protein interaction); and computational modelling, sometimes at very large scale. Models may be static or dynamic, and may focus on mechanistic details or phenotypic outcomes (Csermely *et al.*, 2013). Important data sources include the Kyoto Encyclopedia of Genes and Genomes (KEGG) and Reactome. The Dialog for Reverse Engineering Assessments and Methods (DREAM project) is a CASP-like competitive evaluation in computational systems biology.

Ontologies

The Gene Ontology models knowledge in molecular and cell biology in three hierarchies: Biological Process, Molecular Function, and Cellular Component (The Gene Ontology Consortium, 2012). Other biological ontologies model knowledge about *e.g.* specific organisms, types of molecules, pathways, phenotypes, diseases and experimental methods. GO and some others follow the Open Biomedical Ontology description format. *Gene set enrichment analysis* provides statistical tests of the over- or under-representation of ontology terms in the results of an experiment, compared with their frequency in a background.

Bio-Image Informatics

Bio-image informatics focuses on the capture, management, annotation, analysis and visualisation of data generated by light and electron microscopy, electronic imaging and related technologies. Image data can be static or dynamic, and are often large (Walter *et al.*, 2010). Consensus remains to be developed on metadata standards. Application areas range from the molecular scale through cell structure, tissues, organ systems and whole organisms and include informatic methods in support of histopathology, high-throughput screening, medical imaging, particle tracking and single-particle analysis.

Societies and Journals

The scientific journal *Computer Applications in the Biosciences* adopted the title *Bioinformatics* from 1998. Other important journals include *BMC Bioinformatics*, *Briefings in Bioinformatics*, *IEEE/ACM Transactions on Computational Biology and Bioinformatics*, and *PLoS Computational Biology*. The main international scientific society in bioinformatics is the International Society for Computational Biology (ISCB), which sponsors annual conferences including Intelligent Systems in Molecular Biology, the International Conference on Research in Computational Molecular Biology, ISCB Asia, and Pacific Symposium on Biocomputing. Other important conference series include Asia Pacific Bioinformatics Conference, European Conference on Computational Biology, International Conference on Bioinformatics, and International Conference on Genome Informatics. Many other well-regarded societies, conferences and journals now offer a bioinformatics section.

FUTURE RESEARCH DIRECTIONS

The rapidly increasing affordability of genome sequencing is driving new fields of personalized genomic health care and medicine, and opening unprecedented opportunities in areas as diverse as anthropology, forensics, plant and animal breeding, industrial biotechnology, and environmental management. Bioinformatic challenges across these application domains include the management of immense quantities of diverse data, sometimes in secure environments (*e.g.* to protect patients or intellectual property); highly scalable algorithms and tools especially for networks, systems and populations; and the ability to overlay geospatial coordinates and temporal models. Many important datasets are already too large to be moved, and new types of bioinformatic tools and infrastructure are being trialled that take analyses to the data (*e.g.* in the cloud) rather than vice-versa. The most-

pressing and difficult challenge continues to be the education and training of personnel who can work across the component disciplines of bioinformatics to solve ever more-complex biological problems, while enriching information science and technology.

CONCLUSION

As foreseen by Nobel Laureate Walter Gilbert (Gilbert, 1991), biology has substantially become an information science. At the same time, the richness of problems and ever-growing deluge of data across modern biology is increasingly transforming information science and technology into a living science in the most literal sense.

Bioinformatics is now an indispensable enabling technology at the interface of bioscience with mathematics, statistics, computer science, and information science and technology. This is seen most dramatically in genomics and the other “omic” sciences, which continue to be driven by ever-larger data and the need for integrative analysis of complex biological systems. Specialty areas continue to evolve within bioinformatics to support the study of gene regulation, biomolecular and cellular structure, drug discovery, molecular evolution, bio-imaging and other application domains. Standards, policies and a network of large international bioinformatics centres ensure that biomolecular data are well-managed, openly available for re-use, and in many cases integrated into value-added data services.

KEY TERMS AND DEFINITIONS

Epigenetics: The study of heritable changes in gene expression or phenotype that do not arise from changes in the nucleotide sequence of the genome.

Gene Expression: The process in which information in a gene is transduced to yield one or more gene products (proteins and/or non-protein-coding RNAs).

Genomics: The study of the totality of genetic information in a cell or organism.

Metagenomics: The study of the genetic information in a sample of a mixed community, for example from soil, water, or the intestinal tract of an animal, without prior separation of the constituent organisms.

Omics (or ‘Omics): Genomics, transcriptomics, and other fields of biology characterised by the study of the totality of a class of molecule (*e.g.* proteomics), process (*e.g.* metabolomics) or traits (*e.g.* phenomics) in a cell or organism.

Phylogenetics: The study of genetic relationships among molecules, organisms or taxa over time.

Synthetic Biology: The engineering design and construction of new or modified functions in biological systems.

Systems Biology: The study of networks of interactions among the components of a biological system, emphasising a synthetic, non-reductionist approach and emergent properties.

Transcriptomics: The study of the totality of the RNA molecules arising from the expression of genes under specified conditions.

Bioinspired Solutions for MEMS Tribology

INTRODUCTION

Micro-Electro-Mechanical Systems (MEMS) are miniaturized devices that perform intelligent functions. They can be classified as: (i) sensors based, which have sensing elements and (ii) actuators based, which have elements that undergo mechanical motion. Micro-motors/engines, micro-gears and micro-shutters are examples of actuators based devices. Figure 1 shows a micro-gear made from silicon (http://www.sandia.gov/mstc/_assets/images/mems/gallery/gears/1.jpg). In these devices, tribological issues such as adhesion, friction and wear strongly manifest, which undermine the mechanical motion of MEMS elements (Kim, Asay, & Dugger, 2007). Therefore, it is imperative to solve these tribological issues in order to realize smooth operation and increased operating lifetimes of actuators based MEMS. Conventionally, thin films/coatings have been researched for their application to MEMS as solutions to mitigate the tribological issues. Examples include self-assembled monolayers (SAMs), diamond-like carbon (DLC) coatings, polymers and perfluoropolyether films (PFPE) (Bhushan, 2001). In recent years, bioinspired approaches have attracted attention as better alternative solutions for MEMS. This chapter highlights bioinspired approaches that are promising tribological solutions for actuators based MEMS devices.

BACKGROUND

MEMS are built at micro/nano-scale. At these scales, the ratio of surface area to volume is high.

Figure 1. MEMS micro-gear made from silicon. (http://www.sandia.gov/mstc/_assets/images/mems/gallery/gears/1.jpg). In MEMS devices, tribological issues such as adhesion, friction and wear strongly manifest and undermine the mechanical motion

Hence, body forces such as inertia and gravity become insignificant. In contrast, surface forces such as capillary, van der Waals, electrostatic, and chemical bonding dominate. These surface forces cause adhesion at the interface of contacting MEMS elements. Amongst these forces, the capillary force that arises due to the condensation of water from the environment is the strongest. Further, adhesion strongly influences friction at micro/nano-scale (Maboudian & Howe, 1997). The magnitude of these surface forces is comparable with those that drive the motion of MEMS elements, thereby rendering the elements completely inoperable. MEMS are traditionally made from silicon due to availability of the

DOI: 10.4018/978-1-5225-2255-3.ch038

process knowledge developed for the material in semiconductor industries. However, silicon does not have good tribological properties (Bhushan, 2001). Silicon due to its inherent hydrophilic nature experiences high surface forces, and because of its brittle nature it undergoes severe wear. Thus, the improvement of tribological performance of silicon is the key to realize the smooth operation of actuators based MEMS. Williams and Le have presented an excellent review on the tribological issues in MEMS devices (Williams & Le, 2006).

Tribological properties of materials at micro/nano-scale are evaluated using atomic force microscopes (AFM) and micro-tribo testers. With these instruments, contact conditions similar to those in MEMS can be easily simulated (loads $\sim$ nN to μ N-mN; area $\sim$ few hundreds of nm²).

CONVENTIONAL SOLUTIONS

The gap between moving elements in MEMS is usually about few microns. Hence, solid lubricants (e.g. graphite, MoS₂, WS₂) or liquid lubricants (e.g. oils, greases) cannot be applied in MEMS devices as their sizes are of the same order as those of MEMS elements. Due to this reason, thin films/coatings with thickness less than few microns have been investigated for their application as 'boundary lubricants' for MEMS. Table 1 shows the water contact angle (CA) values, nano-scale adhesion force and nano-scale friction coefficient (μ_n) of silicon (Yoon et al., 2005). The table also shows CA values and nano-tribological properties of thin films/coatings, namely diamond-like carbon (DLC), Z-DOL (commercial name for perfluoropolyether, PFPE), and OTS (octadecyltrichlorosilane) SAM (Yoon et al., 2005; Liu & Bhushan, 2003; Liu, Ahmed, & Scherge, 2001; Singh & Yoon, 2007). The adhesion values given in the table were obtained from force-distance curves measured using AFM. In some cases, the values are taken from the negative intercepts in the friction force versus normal load plots. The

nano-scale friction coefficient (μ_n) is estimated as the slope of friction force versus normal load.

Surface energy of a material is indicated by the contact angle between a water droplet and its surface (water contact angle is inversely proportional to surface energy (Bain, Evans & Whitesides, 1989). From Table 1, it is seen that the adhesion values of the test materials are inversely dependent on their CA values. Silicon is hydrophilic in nature and thereby it supports strong capillary force that causes high adhesion. This in turn increases its friction, which retards the motion of actuators. In contrast, DLC, Z-DOL and OTS have higher CA values. This means that they have lower surface energies and sustain lower surface forces. When applied to actuators these materials are capable of promoting smooth motion.

Table 1 shows micro-scale friction coefficient (μ_m) and durability (i.e. the number of cycles for the onset of wear) of the test materials (Yoon et al., 2005; Liu & Bhushan, 2003; Liu, Ahmed, & Scherge, 2001; Singh & Yoon, 2007). At micro-scale, silicon undergoes severe wear within a short duration of time, i.e. it has low durability (< 100 cycles). Figure 2 shows a worn surface of silicon tested at micro-scale. Wear in the case of DLC, Z-DOL and OTS begins only after hundreds of cycles of sliding, which indicates good durability. These boundary lubricants have distinct mechanisms that promote good tribological properties. By nature they are semi-hydrophobic/hydrophobic, due to which adhesion and friction get reduced to a great extent. In DLC films, in addition to their semi-hydrophobic nature, the formation of transfer layer on the counterface surfaces lowers friction and wear (Erdemir et al., 1996). Z-DOL has fluorine atoms which makes its hydrophobic. Fluorine atoms have larger van der Waals radii that support molecular scale order under shear thereby making Z-DOL a good lubricant (Bhushan, 2001). In OTS, the molecular chains act as molecular springs and reduce friction (Liu & Bhushan, 2003). When these boundary lubricants are applied to silicon MEMS, the tribological performance of the devices can be considerably enhanced.

Table 1. Water contact angle (CA) values, nano-scale tribological properties (adhesion force (nN), friction coefficient (μ_n)) and micro-scale tribological properties (micro-scale friction coefficient (μ_m), durability (n)) of silicon and various thin films/coatings, taken from literature

Nano-Scale Tribological Properties

Figure 2. Worn surface of silicon tested at micro-scale. At micro-scale, silicon undergoes wear within a short duration of time, i.e. it has low durability

WATER REPELLENT SURFACES

Lotus leaves are superhydrophobic with CA of about 162° (Neinhuis, Barthlott, 1997). This property is an effect of the hierarchical structures

on the leaves. Figure 3 shows the surface of a lotus leaf with micro-scale protuberances. The superhydrophobic property is induced by the dual-scale surface roughness from the micro-scale protuberances and waxy nano-crystals. The unique

characteristic of lotus leaves to avoid getting wet is popularly known as “Lotus Effect”. Colocasia is another water repellent plant having CA of about 164° (Neinhuis, Barthlott, 1997). Superhydrophobicity of water repellent plants arises due to the heterogeneous/composite wetting of water, wherein water drops sit on top of the protuberances with air trapped in between them, reducing the solid contact area with the water drops. By mimicking the features present on lotus leaves, scientists have created water repellent surfaces for various applications such as mirrors, car windows, computer/notebook key boards, building structures, fabrics etc., (Gould, 2003).

BIOINSPIRED SOLUTIONS

At micro/nano-scale, friction is in a regime where the contribution from intrinsic/inherent adhesion can outweigh that from asperity deformation (Maboudian & Howe, 1997). Thus, in reducing adhesion, friction also gets reduced, and therefore solutions to reduce adhesion are the key to real-

ize smooth motion between elements of MEMS devices. Further, the effective route to mitigate adhesion is by reducing capillary force at the interface. This can be achieved by learning from ‘lotus effect’. Friction at micro/nano-scale depends on real area of contact (Yoon et al., 2005). Therefore, any reduction in real contact area between surfaces directly reduces adhesion and friction. By creating surface features i.e. topography similar to that seen on lotus leaves (which reduces the contact area between water drops and their surfaces) solutions to reduce surface forces in MEMS can be realized.

As a pioneering work, nano-scale polymeric patterns on silicon surfaces that mimic the protuberances on lotus leaves were fabricated by capillary force lithography, and investigated for adhesion and friction at micro/nano-scale (Yoon et al., 2006). Figure 4 shows a representative image of polymeric nano-patterns on silicon. CA values indicated that the nano-patterns were hydrophobic (Table 2). AFM measurements showed that the nano-scale adhesion and friction of the patterns was significantly lower than those of silicon and PMMA thin film (Table 2). The

Figure 3. Surface of a lotus leaf with micro-scale protuberances. The micro-scale protuberances and waxy nano-crystals on it make the lotus leaf surface superhydrophobic

Table 2. Water contact angle (CA) values, nano-scale tribological properties (adhesion force (nN), friction force (nN)) and micro-scale tribological property (micro-scale friction coefficient (μ_m), durability (n)) of silicon, PMMA, DLC and various nano/micro-patterned surfaces, taken from literature

superior tribological performance of the patterns is due to hydrophobicity and reduced real area of contact between their surfaces and AFM tips. To note, patterning of surfaces causes a reduction in contact area when the size of the asperities (patterns) is considerably smaller than that of the counterface (AFM tips). An investigation by Burton et al. clearly highlights the influence of pattern size (aspect ratio), counterface tip size and relative humidity on the magnitude of surface forces in polymeric patterns (Burton & Bhushan, 2005). Polymeric nano-patterns have excellent tribological properties at nano-scale, however they do not have good load bearing capability at micro-scale. At micro-scale, under micro-loads (μN -mN) polymeric ‘micro-patterns’ exhibit low friction and good load bearing capability (Table 2) (Singh et al., 2007). Figure 5 shows a representative image of polymeric micro-pattern from the direct replication of the surface of natural lotus (*Nelumbo nucifera*). The larger size of the micro-patterns and the increased distance between

the micro-patterns together contribute towards reducing the contact area significantly resulting in lower friction.

Polymeric patterns undergo elastic and/or plastic deformation under relatively higher normal loads. Such deformation result in higher contact

Figure 4. A representative image of polymeric nano-patterns on silicon. These patterns mimic the surface topography of a lotus leaf

*Figure 5. A representative image of micron-sized polymeric pattern from the direct replication of the surface of natural lotus (*Nelumbo nucifera*). These micropatterns contribute to large reduction in friction under micro-loads*

areas and increase the magnitude of surface forces. An effective way to avoid deformation is to pattern surfaces that are harder and stiffer. Examples of such surfaces include micro/nano-textures produced by UV assisted/aluminum-induced crystallization of amorphous silicon (Zou et al., 2005; Nair & Zou, 2008) and DLC nano-dots surface (Singh et al., 2011). DLC nano-dot surfaces are created by depositing DLC films on nano-sized nickel (Ni) dots fabricated on silicon wafers by annealing Ni thin films. The nano-dot surfaces are hydrophobic and reduce adhesion and friction forces significantly (Table 2). Unlike polymeric nano-patterns that have uniform height and are spaced equidistant, the DLC nano-dots are randomly distributed and have un-equal heights. Due to their un-equal heights, only those nano-dots that are taller come in contact with the counterface, thereby resulting in smaller contact areas that lower adhesion and friction. Nano-dots can withstand micro-loads as they are relatively harder and stiffer than polymeric patterns.

Combination of surface patterning and boundary lubrication proves to be more effective in minimizing surface forces. Examples include polymeric patterns with perfluorodecyltriethoxysilane (PFDTES) SAM (Burton & Bhushan, 2005), silicon micro-pillars coated with DLC/ZDOL (Table

Figure 6. DLC nano-dots surface. The surface significantly reduces adhesion and friction

2) (Singh et al., 2011) and textured surfaces of Ni films coated with PFPE (Wang et al., 2014). For a detailed discussion, readers are suggested to refer the book (Sinha, Nalam & Lim (eds.), 2013).

COMPARATIVE NOTE

Figures 7 and 8 show the nano-scale friction and micro-scale friction coefficient (μ_m) of polymeric patterns in comparison with those of silicon, DLC and diphenyldichlorosilane (DPDC) SAM (Singh & Yoon, 2007). From these figures, it could be seen that the bioinspired patterns have relatively lower friction property when compared to the rest of the test materials. Bioinspired tribological surfaces have two fold advantages over the conventional solutions i.e. boundary lubricants (DLC, Z-DOL, SAMs) namely:

1. Ease of application and
2. Effectiveness in reducing surface forces.

As for the first aspect, boundary lubricants have to be applied to MEMS surfaces externally i.e. via dip coating process, physical/chemical vapor deposition etc. Thus, application of boundary lubricants and ensuring their uniform coating/coverage throughout the surfaces of MEMS elements has remained a major challenge. In contrast, bioinspired patterning of surfaces of MEMS ele-

ments can be easily achieved by using the same lithography techniques that are used to fabricate MEMS elements. Moreover, surface patterning can be done verily during the fabrication of the MEMS surfaces. This makes the patterning route more time-effective and cost-effective. Further, in the case of boundary lubricants complex chemistry has to work to make them effective in reducing the surface forces. For example, the tribological performance of SAMs depends on the suitable selections of end groups and chain length. In the case of DLC thin films, the choice of sp^3/sp^2 ratio and the mechanical properties determine their tribological performance. On the other hand, for patterns simple geometric parameters such as height, diameter and pitch (distance between any two adjacent features) define their tribological behavior. By varying these simple geometric parameters, surface forces can be easily controlled.

FUTURE RESEARCH DIRECTIONS

Till date, simple patterns/textures have been investigated for their micro/nano-scale tribological properties for MEMS applications. These surfaces are hydrophobic in nature and reduce surface forces considerably. For more effective reduction in surface forces, patterns with hierarchical structures

Figure 7. Nano-scale friction of polymeric patterns in comparison with those of silicon, DLC and diphenyldichlorosilane (DPDC) SAM

Source: Singh &, Yoon, 2007

Figure 8. Micro-scale friction coefficient (μ_m) of polymeric patterns in comparison with those of silicon, DLC and diphenyldichlorosilane (DPDC) SAM

Source: Singh & Yoon, 2007

(2 tier) need to be investigated. Some examples of hierarchical structures that are of interest are nano-engineered multiscale hierarchical structures with tailored wetting properties (Jeong et al., 2006) and biomimetic, hierarchical structures fabricated on polymer surfaces by sequential imprinting (Zhang, Chan & Low, 2008). Patterns with hierarchical structures give rise to superhydrophobicity, and such topography in combination with boundary lubrication has the potential to greatly reduce surface forces at micro/nano-scale.

CONCLUSION

Bioinspired surfaces have proved to be effective in reducing adhesion and friction at micro/nano-scale and have paved a new way of addressing the tribological issues in MEMS devices. Examples presented in this chapter clearly show that the biomimetic engineering of surfaces is an exciting and practical way to control surface forces. Patterning of surfaces in combination with boundary lubrication can be pursued to control surface forces effectively for the application in miniaturized devices.

KEY TERMS AND DEFINITIONS

Adhesion: It is the tendency of surfaces to cling/stick to one another. Materials with higher surface energy exhibit higher surface adhesion and vice versa.

Biomimetics: It is the use and implementation of concepts and principles found in nature/natural materials for man-made technology.

DLC (Diamond-Like Carbon): It is a class of amorphous carbon material that has certain properties similar to that of diamond (e.g. hardness). Usually it is applied to surfaces in the form of thin films/coatings by physical/chemical vapor deposition techniques. DLCs are semi-hydrophobic and are good lubricant materials.

Friction: It is the resistance to motion. It is the resistance that one surface encounters when moving over another. Friction causes loss in energy.

Lotus Effect: It is the phenomenon of super hydrophobicity and self-cleaning displayed by the leaves of lotus plant. The unique characteristic of lotus leaves to avoid getting wet is due to the presence of micro-protuberances and waxy nano-crystals on the lotus leaves surfaces.

MEMS (Micro-Electro-Mechanical Systems): They are micro/nano-scale devices that perform sensing and/or actuating functions. They are made using the techniques of microfabrication. Silicon is the most popular MEMS material.

Real Contact Area: It is the real area of contact between two surfaces that are in contact under tribological conditions. The real contact area constitutes the areas where asperities of the contacting surfaces meet. The real area of contact is lower by 3 to 4 orders of magnitude when compared to the apparent area of contact (geometrical area).

SAMs (Self-Assembled Monolayers): They are molecular assemblies of organic molecules, which are formed on surfaces by adsorption or chemical grafting. The thickness of SAMs is typically in the range of few nanometers to tens of nanometers.

Tribology: It is the science and engineering of interacting surfaces in relative motion. It encompasses the study and application of the principles of friction, wear and lubrication.

Wear: It is the unintentional material removal/loss under relative mechanical motion between contacting surfaces.

Building Gene Networks by Analyzing Gene Expression Profiles

Crescenzo Gallo

University of Foggia, Italy

INTRODUCTION

Since the detection of the composition of DNA our understanding of biological structures and processes has expanded to a great extent, mostly thanks to computer science which plays a fundamental role in the field of bioinformatics. The main target at present is to analyze and employ the huge amount of accessible data. It is particularly important to distinguish various diseases through useful selection of gene indicators for morbid state and information about the possible correlations between genes.

Data analysis is seen as the largest and possibly the most important area of microarray bioinformatics to obtain the above said targets. Some specific data analysis methods address the fundamental scientific questions about microarray data, that is:

1. Which genes are differentially expressed in one set of samples relative to another,
2. What are the associations between the genes or samples being observed, and
3. Is it possible to group samples based on gene expression values?

In the next section, we illustrate the basic concepts underlying the previous questions and the bioinformatics research. Then we describe the methods for the first of these questions: the search for differentially (up or down) expressed genes. The following sections address the other two topics of clustering and classifying gene profiles. In the end, we show some concerns and issues of interest for future study and development in the field of (microarray) bioinformatics.

BACKGROUND

Gene expression profiling is an extensively used method in the analysis of microarray data. The leading hypothesis is that genes with similar expression profiles are co-regulated and are probably connected functionally.

Cluster analysis helps reaching these objectives; in particular, gene expression clusters help typify unknown genes assigned to the cluster by those genes that have a known function, and are the support for distinguishing common upstream regulatory sequence elements (Brazma *et al.*, 2000).

Clustering of expression profiles and functional grouping is especially compelling if the complete gene set is known. Hence, we used the large publicly available data set included in the Stanford Yeast Database at <http://genome-www.stanford.edu> for our clustering study.

Many applications aim at the molecular classification of diseases based on gene expression profiling and clustering. See, for example, works on leukemias (Golub *et al.*, 1999) and B-cell lymphomas (Alizadeh *et al.*, 2000). These and other studies confirm the usefulness of microarray bioinformatics for scientific and industrial research.

Gene Expression Profiling

Having M array probes with N samples (time points, patient tissues, *etc.*), you construct an $M \times N$ data matrix (the *gene expression matrix*), where the M rows describe the gene expression values across the experiments and the N columns (samples) describe the experiments across the

gene set. Practically, each gene is assigned a set of (possibly normalized) numerical values (the *gene expression profile*) corresponding to the gene's "presence" in each sample.

Then, an $M \times M$ similarity matrix is obtained by calculating the "closeness" between each gene pair with values inversely proportional to the relative (expression profile) distance. Typically Pearson correlation, Spearman's rank correlation, Hamming distance, Euclidean distance and mutual information are employed as similarity measures (Jain & Dubes, 1988; Mirkin, 1996), each having its specific advantages and disadvantages.

The (normalized and possibly log-transformed) expression profiles of thousands of genes are first examined under the typical two-fold comparison (between the same patients in *control vs treatment*, or between two different groups of patients), in order to identify differentially expressed genes. This can be done using an appropriate statistic (*t*-statistic, Wilcoxon, Mann-Whitney depending on the type of comparison) to compare gene expression variability.

Then selected genes are clustered in order to find groups of co-regulated genes.

The clustering output in the end serves as the basis for typifying the role of undetermined genes by means of information available from known genes, to recognize supposed regulatory elements in the early regions of the genes in the same clusters and reduce redundancy and generate averaging profiles in the context of regulatory networks.

Cluster Analysis

Cluster analysis (Duda *et al.*, 2001; Jain & Dubes, 1998; Jain *et al.*, 1999) can be summarized as follows. Let n experimental outcomes $x_i \in \mathbb{R}^m$ ($i=1..n$; each point has m components): the objective is to identify the underlying structure of the data, partitioning the n points into k clusters in order to group in the same cluster points "closer" to each other than to points belonging to different clusters.

In the above statement no clear definition exists for "closer" points, and this depends on the

resolution at which the data are viewed. The last issue is typically addressed by generating a tree of clusters (a dendrogram), whose number and structure depend on the resolution that is used.

Two of the most common methods of clustering gene expression data are hierarchical clustering and k -means clustering (Geraci *et al.*, 2009; Jain *et al.*, 1999).

Hierarchical clustering is the most used, and produces a representation of the data with the most similar patterns grouped in a hierarchy of subsets. This method, however, suffers from considerable problems when applied to data containing a significant amount of *noise*, revealing itself of low applicability. In this case the solutions may not be unique and be data-order dependent. Mathematically, hierarchical clustering involves computing a matrix of all distances for each expression measurement in the study, merging and averaging the values of the closest nodes, and repeating the process until all nodes are merged into a single node.

K -means clustering involves generating cluster centers in n -dimensions and computing the distance of each data point from each of the cluster centers. The data points are assigned to their closest cluster center. A new cluster position is then computed by averaging the data points assigned to the cluster center. The process is repeated until the positions of the cluster centers stabilize.

UNSUPERVISED NEURAL NETWORKS

Artificial Neural Networks can be used not only for prediction but also for data classification. Unlike regression problems, where the goal is to produce a particular output value for a given input, classification problems require labeling of all data as belonging to one of n known classes. These classification models are typical cases of supervised networks, in which it is a priori possible to associate data to clusters and to train the neural network for the classification of further data.

Figure 1. Metaphor of the hyper-surface for the unsupervised neural network

However, there are cases in which the association is not known before. It is then up to the neural network to independently find the associative structures between data, grouping them in clusters. These neural networks are known as *unsupervised* or *self-organizing* (associative memories).

There is not, therefore, a *correct* output as there is not an *erroneous* output. This involves careful observation and analysis by the researcher. In fact, after an unsupervised network has been trained, it must be tested in many directions as it is important to understand what are the data structures resulting from the neural network itself.

An unsupervised network can be compared to a hypersurface in the n -dimensional space, with m “valleys” or minima corresponding to the desired shape of the outputs. The presentation of an input $X_i = \{x_{i1}, \dots, x_{in}\}$ to the network is equivalent to putting a weight in the corresponding point on the surface, thus making it fall into the nearest valley, corresponding to $Y_i = \{y_{i1}, \dots, y_{im}\}$. Obviously, an input X_i' “similar” to X_i — according to some similarity criterion — should fall into the same depression, drawing by association (hence the

term “associative memories”) the same output Y_i (Cammarata, 1990).

Practically, an unsupervised neural network consists of a number of *codebook vectors* Y_i which constitute the center of each cluster. They are the same size of the input space, and their components are the parameters of the unsupervised network. The codebook vectors are the network’s neurons. Some parameters help in training the neural network. The position of the vectors should be adjusted so that the average Euclidean distance between the data points and the corresponding codebook vector should be minimal (Yanai & De Lisi, 2002).

If you also minimize the distance between codebook vectors, the unsupervised network is known as Self-Organizing Map (SOM) or Kohonen network (Herrero *et al.*, 2001).

DIFFERENTIAL GENE EXPRESSION

This section illustrates a variety of methods, ranging from classical and more modern statistical

Figure 2. Example of paired (a) and unpaired (b) data

theory, to give a detailed path for finding differentially expressed genes in DNA microarray data. Let's start by illustrating the meaning of "differentially expressed genes".

DNA microarray data is made of a matrix of numerical values of gene expression levels taken from various patients' samples. We aim at recognize genes that are differentially (i.e., more or less) expressed under some different experimental conditions (ill and healthy patients, before and after some therapy).

Usually, each gene in the microarray is inspected to decide whether or not it is differentially expressed, typically doing this by studying many individual genes in parallel. This differs from the clustering and classification methods of the next sections, which are specifically interested in the interactions between the genes under investigation.

We will now show how expression data can be reshaped and examined for discovering differentially expressed genes.

In paired data there are two measurements from each patient, one before and one after treatment (Figure 2a). To determine whether a gene has been up- or down-regulated after treatment, you may compute the "after/before" fold ratio by considering the log-transformed values. This allows you to simply subtract (and not divide) the "after" from the "before" value, thus obtaining a set of single values whose mean (or median) you want to know if it is different from zero.

In unpaired data (Figure 2b) there are two (independent) groups of patients, and you search for those genes differentially expressed between the two groups. For each patient from each group there is a gene expression value; you want to know whether the mean (or median) of the two groups is different.

If you have a data set with more than two groups then a more complex approach, typically the analysis of variance (ANOVA), is required.

THE "RELAXED" CLUSTERING ALGORITHM

Preliminaries

The interpretation of the large amounts of data produced by DNA microarray techniques for the analysis of gene expression requires new efficient strategies to reduce the size involved. Clustering algorithms typically group genes (or samples) in clusters of similar expression profiles to identify possible functional relationships between them. Of particular importance are graphical representations of the clusters and their *automatic* annotation from available genome databases (Eisen *et al.*, 1998; Furey *et al.*, 2000; Golub *et al.*, 1999; Pe'er *et al.*, 2002; Wu *et al.*, 2000; Zhou *et al.*, 2002). Similar problems are found in the analysis of large networks, where you try to extract subnets that

meet certain criteria (such as the search for web pages on the same subject) (Eckmann & Moses, 2002; Jenssen *et al.*, 2001; Milo *et al.*, 2002; Shen-Orr *et al.*, 2002; Butte *et al.*, 2000; Yanai & De Lisi, 2002).

Here we analyze an algorithm, based on correlation graphs, that combines network analysis with the classical clustering for the study of DNA microarray data. The algorithm depends on two parameters (the *correlation* and *clustering* thresholds), resulting in an effective ability to analyze the sensitivity of the results in response to the particular configuration chosen.

The algorithm is based on the concept of “curvature” (Eckmann & Moses, 2002; Watts & Strogatz, 1998) applied to the network (correlation graph) of co-expressed genes, where the nodes are the genes (or samples) and the edges represent the co-expression between linked genes. Then a certain number of clusters are identified that correspond to connected components of the graph with a high clustering index, defined as the local density of triangular relations (Collet & Eckmann, 2002). The clusters of genes (or samples) are the densest regions of the correlation graph; communities with high clustering index are low-entropy structures, with obvious biological relevance.

The algorithm has been implemented in *Mathematica* (due to its intrinsic computational power and functional paradigm) and applied to some publicly available datasets: *Saccharomyces cerevisiae* (Eisen *et al.*, 1998) and DLBCL lymphoma (Alizadeh *et al.*, 2000). The computational performances obtained are comparable to those required by Hierarchical (Jain *et al.*, 1999) and Markov Clustering (Van Dongen, 2000).

The Clustering Algorithm

A set of DNA microarray data consists of expression levels of N genes in M different experimental conditions (RNA samples). The algorithm (based on the correlation graph approach) is articulated according to the following steps.

1. Read input DNA microarray data X .
2. The $N \times N$ correlation matrix P is defined on all pair of genes $x_{k,l}$ ($k, l = 1..N$) whose elements are computed using the Spearman's rank correlation coefficient¹:

$$\rho_{k,l} = 1 - \frac{(6 \times S_{j=1,M} d_j^2)}{(n^2 - 1)n} \in [-1, 1]$$

where

$$d_j^2 = x_k(j) - x_l(j).$$

Let θ a fixed threshold defining a range of symmetrical comparison $(-\theta, \theta)$. Construct the square adjacency matrix A between genes whose elements $a_{k,l}$ ($k, l = 1..N$) are defined as follows:

$$\begin{cases} a_{k,l} = 0 & \text{if } \rho_{k,l} \in (-\theta, \theta), \\ 1 & \text{otherwise} \end{cases}$$

3. A correlation (undirected) graph G is constructed from the adjacency matrix, with edge weights equal to the correlation coefficients $\rho_{k,l}$.
4. Each node i of the correlation graph has an associated clustering coefficient $c(i) = 2\alpha / \beta(\beta-1)$, where α is the number of real and β is the number of possible triangular clusters for node i .
5. Let $\gamma \in [0, 1]$ (clustering threshold). From the graph G we induce a subgraph H made of all nodes $i \in G$ (and related edges e) with “relaxed” clustering coefficient $c_r(i)$ greater than or equal to γ .

$$H = \{\text{nodes } i \in G \text{ and related edges } e: c_r(i) \geq \gamma\}$$

The “relaxed” clustering coefficient for a node i is given by the maximum among its clustering coefficient $c(i)$ and those of the nodes directly connected to it: this gives a “tethering” effect by the surrounding nodes, better taking into account the complex structure of the relations between the

(correlation) graph nodes than the simple clustering coefficient of each node.

6. From the subgraph H we extract all connected components (made of at least two linked nodes) representing the classes (clusters) identified by the values chosen for thresholds (algorithm's parameters) θ and γ .

To better understand how the algorithm operates with thresholds θ and γ you may think of the initial graph G as a mountain range. The clustering threshold γ is the fog extending up to a certain height and clusters are emerging mountain peaks. Varying the correlation threshold θ means changing the soil structure, while γ only raises or lowers the fog level and, therefore, modifies the existence and relative size of clusters.

ANALYSIS OF GENE EXPRESSION PROFILES: EXAMPLES

Analysis of Gene Expression Profiles in *Saccharomyces Cerevisiae*

Figures 3 and 4 represent the computed results based on the expression profiles of 6,221 *Saccharomyces* genes, crossed with 80 available samples. Even with relatively high values of correlation and clustering we obtain well-defined clusters. Figure 1 represents the final subgraph with correlation $\theta = 0.90$ and clustering $\gamma = 0.70$ derived from an initial graph with 1,917 links. Note that only 237 of 6,221 genes (3.81%) have a nonzero clustering coefficient. Figure 2 shows the subgraph corresponding to $\theta = 0.80$ and $\gamma = 0.64$ starting from 19,026 links, with 1,112 genes (17.87%) showing nonzero clustering coefficient.

Many of the obtained clusters have an acceptable biological basis. For example, Cluster #7 of Figure 3 and Cluster #13 of Figure 4 contain (with obvious differences) almost all the genes for the production of histones: This cluster is quite stable against the variation of threshold parameters. Larger clusters have also been detected, such as

the cluster of protein synthesis (Cluster #10 of Figure 3 and #2 of Figure 4). The latter is likely to vary substantially with varying thresholds, and can end up with including hundreds of genes.

Figure 5. shows a visual comparison of a particular cluster belonging to graphs of Figures 3 and 4. This comparison shows how the two-dimensional clustering analysis here implemented with correlation graphs poses a greater resolution detail in carrying out the clustering of the genes involved. This turns out to be an important factor for an adequate biological study, eliminating during analysis those links between genes that appear to be not too strong to resist a greater resolution level.

Analysis of Gene Expression Profiles in *Lymphoma*

Graphs in Figures 6 and 7 represent the results based on expression profiles of 4,026 lymphoma genes crossed with 96 available samples. Both graphs have a correlation threshold $\theta = 0.80$, with 568 of 4,026 genes with nonzero clustering coefficient (14.11%) and 1,872 initial links.

Classification obtained with $\gamma = 0.40$ shows in Cluster #75 a group of under-expressed genes in CLL (Chronic Lymphocytic Leukaemia) tumors. With $\gamma = 0.24$ Cluster #76 represents a group of over-expressed genes in DLCL (Diffuse Large B-Cell Lymphoma) tumors.

Lymphoma Samples' Analysis of Expression Profiles

Figure 8 shows the classification based on 96 samples of the lymphoma data set (this is the transpose of the gene expression matrix, made of 96 rows and 4,026 columns). The thresholds are $\theta = 0.60$ and $\gamma = 0.30$. There are 17 samples (17.71%) with nonzero clustering coefficient, with 58 initial links. The clusters obtained are clearly identified and are associated with a single sample subtype: Cluster #1 corresponds to T-cells sample, Cluster #2 to FL (Follicular Lymphoma) and Cluster #3 to CLL.

*Figure 3. Correlation graph of genes in *Saccharomyces cerevisiae* with $\theta = 0.90$ and $\gamma = 0.70$*

*Figure 4. Correlation graph of genes in *Saccharomyces cerevisiae* with $\theta = 0.80$ and $\gamma = 0.64$*

Figure 5. A cluster comparison between graphs in Figures 3 and 4

Figure 6. Correlation graph of genes in Lymphoma with $\theta = 0.80$ and $\gamma = 0.40$ 

Clustering Microarray Data with Neural Networks

The clustering analysis with neural networks has been implemented on the same input data on which the classification was carried out using correlation graphs, that is the gene expressions in *Saccharomyces cerevisiae* (Eisen *et al.*, 1998) and DLBCL lymphoma (Alizadeh *et al.*, 2000).

Clustering Gene Expression in *Saccharomyces Cerevisiae*

The search for gene expression clusters in *Saccharomyces* fulfilled through unsupervised neural networks provides the basic tool for performing an additional analysis to that of the correlation graphs. Obviously there are some differences.

Figure 7. Correlation graph of genes in Lymphoma with $\theta = 0.80$ and $\gamma = 0.24$

The analysis carried out with unsupervised neural networks needs to ensure that all possible genes of our original data set are put into predicted clusters. This means classifying 6,221 genes and looking for, in the aggregate source, the biological meaning of that classification.

Figure 9. shows the fitting parameters of the neural network and the average distance obtained. The latter turns out to be 3.8085 and all genes are partitioned into 14 clusters. From this point of view, the correlation graphs' algorithm offers an advantage over the analysis made with neural networks: With the ability to intervene on two thresholds you obtain a greater "filtering" in the analysis of results.

Classification of Lymphoma Samples

In this section we focus on analyzing the lymphoma dataset by observing samples with reference to genes. In this context, Figure 10 shows the characteristic elements of the unsupervised neural network in the various clustering iterations, with an average distance equal to 43.1945.

FUTURE RESEARCH DIRECTIONS

By identifying combinations of genes that "cooperate" in order to obtain specific bio-logical results, it is possible to identify such genes more attractive for future research and, potentially, specific drug targets to improve the quality of the therapeutic tools available. This can be done by:

1. Filtering those genes that are more up/down-regulated (differentially expressed), and thus possibly responsible for outbreak of disease, and
2. Discovering gene groups possibly associated to different pathological states.

To illustrate the performance of the methodology, we applied it to two independent datasets from patients with various disease subtypes. The results show the validity of the proposed approach and the selection of key deregulated genes recently reported in the literature.

CONCLUSION

It is increasingly accepted the hypothesis that complex diseases are the result of events that occur in various ways. Through the development of computational tools that detect the involvement of multiple genes interacting with each other in specific experimental situations, you can provide solutions that go beyond the capacity offered by those dealing with single genes.

In this chapter we illustrate the analysis of DNA microarray data obtained from the expression of multiple genes, using both special parametric clustering (correlation graphs) and classification techniques with artificial neural networks. The greatest usefulness of the classification procedure described here and its computational approach is that it requires no prior knowledge of the specific functions of genes or interactions between them to produce meaningful results. Instead, it represents an appropriate means of exploring genomic “situations” not yet well investigated, a target within the reach of the individual researcher with the power and flexibility of the computing environments now available.

KEY TERMS AND DEFINITIONS

Algorithm: An algorithm is a procedure that solves a given problem by a finite number of steps. A problem solved by an algorithm is said *computable*. The term “algorithm” is derived from the Latin transcription of the name of the Persian mathematician al-Khwarizmi, which is considered one of the first authors to have made reference to this concept.

Artificial Neural Network: ANNs are mathematical models that represent the interconnection between elements defined artificial neurons, i.e. mathematical constructs that to some extent mimic the properties of living neurons. These mathematical models can be used both to obtain an understanding of biological neural networks, but even more to solve engineering problems of artificial intelligence such as those that arise in various technological fields (in electronics, computer science, simulation, and other disciplines).

Bioinformatics: Bioinformatics is a scientific discipline devoted to the solution of biological problems at the molecular level with computer methods. It is an attempt to describe, in numerical and statistical terms, biological phenomena with a

set of analytical and numerical tools. In addition to information technology, bioinformatics uses applied mathematics, statistics, chemistry, biochemistry and concepts of artificial intelligence. Bioinformatics mainly deals with providing valid statistical models for the interpretation of data from experiments in molecular biology and biochemistry in order to identify trends and numerical laws; generate new models and mathematical tools for the analysis of sequences of DNA, RNA and proteins in order to create a body of knowledge concerning the frequency of relevant sequences, their evolution and possible function; and organize the knowledge acquired at the global level of genome and proteome databases in order to make such data accessible to all, and to optimize the data search algorithms to improve accessibility.

Cluster: Natural subgroup of a population, used for statistical sampling or analysis.

Clustering: Clustering or cluster analysis is a set of techniques of multivariate data analysis aimed at selecting and grouping homogeneous elements in a data set. Clustering techniques are based on measures relating to the similarity between the elements. In many approaches this similarity, or better, dissimilarity, is designed in terms of distance in a multidimensional space. Clustering algorithms group items on the basis of their mutual distance, and then the belonging to a set or not depends on how the element under consideration is distant from the collection itself.

DNA: Deoxyribonucleic acid (DNA) is a nucleic acid that contains the genetic information necessary to the biosynthesis of RNA and protein molecules essential for the development and proper functioning of most living organisms. The order in the sequential arrangement of the nucleotides A, T, C, G represents the genetic information, which is translated with the genetic code in the corresponding amino acids.

DNA Microarray: A DNA microarray (commonly known as gene chip, DNA chip, biochip array or high density) is a collection of microscopic DNA probes attached to a solid surface such as glass, plastic, or silicon chip forming an array

(matrix). Such arrays allow to simultaneously examine the presence of many genes within a DNA sample (which often can also represent the entire genome or transcriptome of an organism). A typical use is to compare the gene expression profile of an individual patient with that of a healthy one to identify which genes are involved in the disease.

Gene: The gene is the fundamental hereditary unit of living organisms. Genes correspond to portions of the genetic code localized in specific positions within the sequence (DNA or, more rarely, RNA) and contain all the information necessary for the production of a protein. They are contained and organized within chromosomes, present in all cells of an organism.

Gene Expression: In the field of molecular biology, gene expression profiling is the measure of the activity (expression) of thousands of genes at a time, to create a global picture of cellular function. These profiles can, for example, distinguish between cells that are in proliferation, or show how the cells react to a particular treat-

ment. Many experiments of this type measure an entire genome simultaneously. DNA Microarray technology measures the relative activity of target genes previously identified.

Pattern: In biology with pattern (sometimes “profile”) one refers to different types of regularity, such as the regularity of the biological sequences of DNA or proteins that allow the recognition and specific binding between molecules, or the regularity in the level of expression of the genes of cells which allow the recognition of different experimental cell types including tumor cell types, or the regularity in the events that occur during processes such as the development of an organism, or even the regularities in the behavior of animals.

ENDNOTE

- ¹ Spearman’s rank is more robust than Pearson’s correlation coefficient if there is a non linear correlation between data when data are not normally distributed.

Concerns and Challenges of Cloud Platforms for Bioinformatics

B**Nicoletta Dessì***Università degli Studi di Cagliari, Italy***Barbara Pes***Università degli Studi di Cagliari, Italy*

INTRODUCTION

In recent years, computer advances have played an important role in promoting scientific research in biological areas such as genomics, proteomics and other “-omic” subfields which rely heavily on suitable computational infrastructures for managing large-scale data. In particular, the flood of data from genome sequences has given rise to “bioinformatics”, an interdisciplinary research domain which employs a wide range of computational techniques derived from scientific disciplines (such as statistics, machine learning, applied mathematics etc..) for managing biological data. To get to understand the current application fields of bioinformatics, it is necessary to consider the following aspects.

A first aspect is about the massive production and spread of biological data around the web. Generated within a short period of time and stored in a growing number of web resources, the increasing amount of biological data has introduced new challenges about its management and exploitation.

For example, thanks to next generation sequencing instruments and ICT advances, areas of life sciences that were previously distant from each other (in the ideology, analysis practices, toolkits etc.) are now able to share and analyze data in transparent and reproducible fashion. This interdisciplinary research task calls for the integration of information with multiple levels of granularities from several web resources that often represent information and data in different ways.

In this respect, bioinformatics increasingly deals with providing technical approaches to support interdisciplinary scientific knowledge which relies on working with concepts from different areas in constant evolution and more and more requires experimental techniques, scientific approaches and collaborative management of data (Bosin, Dessì, & Pes, 2007).

A second aspect is about recent advances in computer science that significantly influence the development of computational tools in bioinformatics. Specifically, the service-oriented paradigm has provided a new way of thinking biological resources in terms of computational infrastructures by positioning services as primary functional elements for data integration. Several biomedical organizations (such as the National Center for Biotechnology Information (NCBI) and The National Center for Biomedical Ontology (NCBO)) provide web portals that expose Web services for searching data. Existing techniques for web content classification, search, and visualization seem to be actually inadequate to satisfy the biologist’s needs because accessing these heterogeneous systems from the Internet is not straightforward without the availability of standard and common interfaces.

In this respect, bioinformatics research is devoted to search explicit and automatic ways of joining information to improve the usability of web resources.

Finally, the rapid development of the Internet has provided an opportunity to investigate about

the use of state-of-the-art technology for the construction of a new generation of tools that integrate plain data sources, public programmable APIs and any kind of available services. Usually referred to as Web2.0 applications, these tools rely on open APIs or reusable services. The availability of biomedical ontologies dramatically increases the range of benefits and the usages derived from these applications that often support a deeper analysis of data by taking into account the semantic information (Dessì, Pascariello, & Pes, 2014).

Considering the aforementioned aspects, it is clear that bioinformatics research addresses three main challenges namely:

1. Storing and analyzing large amount of heterogeneous data.
2. Enabling knowledge extraction from several web resources and collaboration through user-friendly interfaces.
3. Promoting solutions for offering different categories of services to end-users.

Nowadays, the cloud computing paradigm represents a primary solution to these challenges as it extends the role of the Internet to enable a new form of distributed system for large-scale data processing.

As significant component of the Web 2.0 world, Cloud computing expresses a service-based architecture where computing services are delivered on-demand to customers over a network in a self-service fashion that is independent of device and its location. This innovative technology enables the introduction of new computational paradigms that could have a great influence on facing the above challenges. The application of cloud computing in bioinformatics is still preliminary, although an increasing number of biological applications is relying on the Cloud for processing large datasets (Calabrese & Cannataro, 2016; Schadt, Linderman, Sorenson, Lee, & Nolan, 2011). Conversely, few work has been done to explore the use of architectural cloud-based solutions (Mrozek, 2015).

This chapter aims investigating the extent to which cloud technology offers a viable platform for developing and deploying applications that support users in searching and integrating information offered by bioinformatics resources. The chapter outlines the basic features that such computing applications should exhibit and the challenging issues they deal with. The architecture and the functionality of the cloud-based environments are presented to stress how cloud platforms could offer added-value service components and flexibility that make their adoption attractive for bioinformatics.

The chapter also sketches some application scenarios that illustrate the potential of cloud-based environments for integrating information from multiple web resources, including biomedical portals.

BACKGROUND ON CLOUD COMPUTING

Cloud technology endows users with a service-based environment that provides hardware and system components and refers to software applications delivered as services over the Internet (Lin, Fu, Zhu, & Dasmalchi, 2009).

Cloud resources are usually organized into bottom-up layers, depending on the type of service:

- **Infrastructure-as-a-Service (IaaS):** Provides suitable hardware, including physical servers and network bandwidth services directly to end users which do not own enough processing power, storage capacity, applications to meet their needs. These resources can be ‘rented’ from a cloud provider on an as-needed basis and accessed from anywhere via an Internet connection. Cloud services employ a metering system that divides the computing resources in appropriate blocks and users pay for the service as an operating expense without incurring any significant initial capital costs.

- **Platform-as-a-Service (PaaS):** Provides a hosting platform in which users are allowed to develop applications without dealing with software issues such as operating system upgrades, implementation of compilers, installation and maintenance of databases etc.
- **Software-as-a-Service (SaaS):** It basically means that the software is available on demand, most of which is browser-based and devoted to a specific function. SaaS applications are often priced by a rental fee, which includes the application software license fees, software maintenance, and technical support costs.

Although provided at different level, Cloud Services communicate with each other and are self-contained i.e. each service provides the same functionality, independently of other services. The global infrastructure offered by a Cloud environment is made possible by abstracting the physical resources (i.e. storage, memory, network etc.) so that multiple operating systems can run on a single hardware platform concurrently. Commonly referred as virtualization, this abstraction is based on technologies that greatly improve resource utilization and offer several key advantages, such as a low entry cost to use compute-intensive resources, a pay-per-use model, a high scalability that is dynamically adjusted according to user demand.

The cloud computing platform composes of thousands or even tens of thousands nodes, which provide mass data storage, management and processing. Because these dynamically scalable and virtualized cloud resources are provided as services, users are not required to have expertise nor knowledge or control over the technological structure that supports their tasks.

THE DRIVING FORCES OF CLOUD COMPUTING IN BIOINFORMATICS

Cloud Computing could offer many *added-value services* that previous solutions do not have. In

fact, the primary difference is that offerings and services are not located in house, but outside the bioinformatics organization. As reported by Chae, Lee, Marru, Lee, & Kim (2013), a significant number of research institutions are experiencing the capacity limits of their computing facilities. Additionally, collecting and configuring suitable tools and resources for certain research purposes is non-trivial job, even for expert developers. By adopting cloud technology, bioinformatics organizations could avoid the installation and management of software on their own computers and benefit from centralized and automatic software updates. The ease of access, to and from cloud-based resources, promotes the use of cloud-based strategies such as MapReduce a run time system which automatically partitions input data and schedules the executions of programs for large datasets in a large cluster of commodity machines (Taylor, 2010).

As well, its open-source implementation Hadoop has a widespread adoption in bioinformatics. Moreover, cloud paradigm promotes the development of biomedical applications specifically designed to take advantage of cloud infrastructure. Meanwhile, new functionality could be provided, the usage of cloud-based services can be scaled up and down smoothly without the need for upfront cost. Finally, cloud technology helps break the barriers between different web applications.

Recent work in bioinformatics addresses the *flexibility* of the services provided at IaaS layer for the deployment of data intensive applications such as processing high throughput sequencing data or executing intensive analysis algorithms (Zhang, Gu, Liu, Wang, & Azuaje, 2012; Hung & Lin, 2013). These applications get as many machines as the analysis of data needs and automatically scale up and down the hardware resources based on dynamic workloads. Conversely, in distributed processing environments, it is difficult to distribute and co-ordinate a large-scale job on different machines, run processes on them and install additional machines to recover if one machine fails. Cloud technologies remove such technological concerns from the users.

A less explored level of cloud services is PaaS which focuses on building applications such that:

1. Draw the necessary resources on-demand (like compute servers or storage),
2. Perform their tasks, and
3. Relinquish the unneeded resources after a task is done.

Everything is automated and operates without any human intervention by taking advantage of simple APIs of Internet-accessible services that scale on-demand.

A relatively few number of bioinformatics applications exists which has been developed at PaaS layer, although PaaS based solutions should be an added value for the biological community. In particular PaaS applications are attractive for small bioinformatics organizations and research groups that are allowed to benefit from the most advanced technology available today at lower costs and lower risk. Indeed, the upfront investment is low, they don't need to invest in software / hardware, licenses and renewal costs are kept to a minimum and they only pay for what they use.

As such, PaaS based solutions can offer a powerful and flexible alternative for bioinformatics applications.

Two significant concerns must be addressed before moving data and bioinformatics applications to a cloud environment: the security of information and the bottlenecks of data transferring.

- **Information Security and Privacy:** The scalability and the easy access to cloud resources increases the risk of security of data that have security requirements out of the ordinary such as medical records, clinical data from human studies etc. The storage of such data on publicly accessible servers requires the definition of security rules to protect data security and privacy. For example, mechanisms such as encryption measures and role-based access control models should be deployed on the Cloud

respecting both the typicality of biological data and the requirements of scientists in sharing such a data. Differently from conventional web-based environments, the use of the Cloud for storing data and applications improves physical security as it enables the creation of separate virtual machines and firewalls for each independent application environment. Security professionals traditionally recommend partitioning a system as a means of protection. The ease of creating new virtual machines provides ways to improve the security of hosted data by partitioning resources into separate areas, conferring protections against attacks.

- **Bottlenecks of Data Transferring:** Cloud vendors store the backups of users' applications and data in multiple geographical locations. Although, cloud can provide extra processing resources during the peaks (within limits), transferring vast amounts of biological data to the cloud is a significant bottleneck in cloud computing (Grossman & White, 2012). Networking bandwidth limitation causes delays in data transfer and incurs high bandwidth costs from service providers. This cost is an important issue for biomedical institutions that require substantial data movement (on the order of terabytes and petabytes) on a regular basis. As a consequence, the use of cloud infrastructure currently does not make economic sense for applications that need to continuously export or import large volumes of data to and from the cloud.

APPLICATION SCENARIOS

Cloud computing has been applied successfully to deal with tasks that require substantial computational power. Some initiatives have already successfully incorporated the cloud to expedite data processing in next-generation sequencing,

comparative genomics and proteomics (Krampis et al., 2012; Sudha Sadasivam, & Baktavatchalam, 2010).

With the emergence of readily available cloud platforms, software developers have the opportunity to move one step closer towards the search and integration of information from the wide range of biomedical web resources.

In exploring these resources, biologists are not interested in the large amount of their content. Conversely, they distill a huge amount of data from multiple web sources in order to obtain key information that focuses on a single class of concepts (e.g., only gene products). Because biological information encompasses many domains of knowledge, the success of the user's depends on his ability in browsing information that is stored in several web sites that exhibit diverse organization, terminology, data formats. For example, consider a user who investigates about the role of thyroid hormones administration in the treatment of the heart failure. He has to translate his problem in a set of concepts that meet the taxonomy of terms defined by the curators of the web resource he navigates. Often, the concepts of interest don't belong to a single taxonomy. Often, the concepts of interest don't belong to a taxonomy exploited by a single web site. In this case, unearthing specialized information from different web resources can be complex, time consuming and daunting. Moreover, the user must learn and remember the navigation paths of each specific web site he visited. Finally, different biomedical web portals implement the same basic functionality and are often concerned with overlapping information.

The design of applications for effectively support the users in searching biomedical resources must consider three fundamental questions. First, how to integrate structured, semi-structured and unstructured available data with diverse and sparse schemas? Second, how to retrieve meaningful information in an easy and efficient way? Finally, how to implement a searching infrastructure which has to scale, hence change, to meet new requirements stemming from the growth of its searching domain?

The adoption of the Cloud computing makes it easy to exchanging and integrating data amongst multiple service providers via high quality, interoperable services offered in a "neutral" territory by the cloud infrastructure. As it happens for web engines, these services act as specialists which search for data exposed by biomedical organizations via public programmable APIs and return real-time information.

These circumstances can be addressed by implementing PaaS applications that broaden the spectrum of use of the cloud paradigm and encloses the adequate environment for building applications that harvest the full potential of this technology. Typically, this programming environment includes components such as programming languages, web servers, and databases that are not lightweight for most biologists or people with no or limited programming experience. A recent major development is Google App Engine (GAE), a PaaS environment that allows users to quickly develop and run any web application on Google's infrastructure while benefiting from Google services, such as search, e-mail, geographic maps and social networking (Google App Engine. Documentation). GAE applications scale as the traffic and the data storage vary. The use of the basic services is free and users pay only for increased level of services that are delivered over network connection. Within GAE, the data management relies on Datastore a NoSQL database which supports data storage service distribution. Unlike a traditional relational database, a NoSQL database supports operations (i.e. create, read, update, delete) to manage structured objects by means of an SQL-like language (Stonebraker, 2010). Typically, PaaS delivers a software environment to deploy and run applications where cloud resources scale automatically and developers do not need to know how many resources are required nor to assign resources manually in advance. As well, the PaaS environment eases the rapid development of new software components and the introduction of new functionality in existing PaaS applications. Indeed, the PaaS applications promote the event-driven integration of data from heterogeneous and

distributed resources by providing convenient and on-demand access to web resources via Web Application Programming Interfaces (API) without the necessity to know where the services are hosted or how they are delivered.

The development of PaaS applications involves substantial changes in the current styles of software development. Specifically, instead of being conceived as a set of procedural tasks, a PaaS application needs to be thought in terms of a framework which undertakes the responsibility of coordinating and organizing the search across different web resources by combining high level services offered by the cloud infrastructure and APIs that satisfy the application requirements.

As an example, BioCloud Search EnGene (BSE) is a PaaS application that facilitates searching and integrating biological information from public and large-scale genomic repositories (Dessi, Pascariello, Milia, & Pes 2014) using web services provided by the National Center for Biotechnology Information (NCBI). Using BSE, users find their information of interest by means of a simple “Google-like” query interface that accepts the standard name of genes as keywords. The design of BSE is centered on the concept of dataspace, a new paradigm for the integration of heterogeneous data coming from a diverse set of sources, without an a priori schema and regardless their format and location (Dong & Halevy, 2007). A dataspace consists of a set of resources, namely the participants, and a set of relationships between them (Argiolas, Atzori, Dessi, & Pes, 2012). A fundamental part of a dataspace is the catalogue that contains information about the URL of the participants. Using suitable services exposed by participants, BSE provides integrated views of data over web resources by following the pay-as-you-go principle: data from participants are accessed as metered resources without the need to store them locally. Conceived as a multi-level index, the catalogue stores identifiers and annotations about genes, acquires and combines information from participants. The BSE’s user interface supports special templates, namely contexts, that hide the complexity of data searching by means of accor-

dions i.e. a vertically stacked list of items. Each item represents a context and can be “expanded” or “stretched” in order to reveal additional contexts associated with it. Contexts are nested: the user who clicks on a gene’s identifier is redirected to a new accordion to explore new information about the searched gene.

FUTURE RESEARCH DIRECTIONS

Currently, the bioinformatics community mainly adopts the Cloud technology for storing and analyzing large sets of biological data. Hadoop (Taylor, 2010) is the most popular tool for organizing data-intensive analysis into cloud-based pipelines that are executed over multiple nodes. However, this approach remains difficult for biologists with limited programming skills. Therefore, future efforts should be devoted to building lightweight cloud environments that do not require extensive coding by keyboard and allow biologists to organize their work easily by drag and drop operations. In recent years, there has been much activity on the development of biomedical portals i.e. on specially designed web sites that bring information together from diverse sources in a uniform way. For example, BioPortal, is a popular web portal that provides access to a library of biomedical ontologies and RESTful Web Services that enable the incorporation of ontology content into software applications. Although the benefits of such portals are well documented, this explosion of biomedical resources generates impediments for researchers and clinicians when they try to discover the most appropriate information for the realization of their goals.

Perhaps, one of the major obstacles is the difference in the structure of portals: each portal has its own organization, terminology and data formats and the users have to expend an amount of cognitive effort in remembering navigation paths. Moreover, many biomedical portals implement the same basic functionality and are often concerned with overlapping information.

Because cloud technologies ease the access to diverse types of web resources via interoperable services, future research directions should face the problem of setting up a system of standards for data exchanges in order to facilitate the implementation of lightweight cloud applications that support data integration.

Over the past few years, WEB 2.0 technologies tried to enhance user interaction by promoting the use of flexible organizational systems (i.e. social networks, blogs and wikis) that have been introduced into current research practices. As well, recent technologies have evolved and new cloud environments are appearing that allow to reformulate the common investigation practices so that they can profit from a paradigm where domain experts (rather than programmers) organize the domain knowledge in a intuitive and collaborative way (Dessì, Milia, Pascariello, & Pes, 2014). From the medical or biological perspective, collaboration is attractive for many circumstances and consists well with the e-Science paradigm that envisions the scientific research carried out via internet (Bosin, Dessì, & Pes, 2011; Bauzer Medeiros & Katz, 2016). So, future research efforts should be directed to build distributed research environments that support autonomy and intelligent coordination of researchers in creating and managing shared data and knowledge.

In recent years the technological world has grown thanks to the incorporation of sensors, microcontrollers and transceivers for collecting and sharing real-world information. Internet of Things (IoT) is an information acquisition paradigm that defines such computer-based environments where each physical object is equipped with devices for interacting with each other and communicating with the users (Chaâri et al., 2016). By enabling continuous and ubiquitous access to information from any connected device over the Internet, IoT is leading to collect large amount of data from scientific experiments in life sciences and bioinformatics without an uniform way to share, process and understand context information. It is evident that IoT will only achieve its full potential

when all the devices will work and learn together without human interaction. Without dedicated functionalities and organizational data structures there is a risk of creating the illusion that scientific advances can be supported by simply making available a greater amount of data. In this respect, it is crucial that bioinformatics starts devoting more attention to cloud technology as a technical structure enabling the organization and the knowledge extraction from these new information sources.

CONCLUSION

Cloud environments contrast sharply with traditional centralized computing platforms that are not only costly, but risk to become increasingly inadequate to meet the requirements of modern biologists. In particular, PaaS level can offer a powerful alternative for building applications that can be re-designed to take advantage of cloud infrastructure. Finally, cloud technology is not only an alternative to the traditional computing environments but occupies an its own niche: it transparently provides the biologists with pragmatic solutions to some open research issues such as big data storing and analytics, knowledge and data sharing, extracting and integrating information from different web resources etc. The above solutions are increasingly being suitable for many biologists and cloud computing is becoming a significant technology for developing a large variety of services which, most important, are exerting revolutionary influences on the whole scientific community.

KEY TERMS AND DEFINITIONS

Application Programming Interface (API):

An API specifies how software components interact in terms of its operations, inputs, outputs, and underlying types in a way that is independent of their respective implementations. APIs allows software developers to build programs as a set of building blocks whose functionality is provided by their corresponding APIs.

Biomedical Ontology: A structured representation of the knowledge by means of formal naming and definition of the types, properties, and interrelationships of the entities that really exist for biological research.

Computer Platform: The computer hardware and the operating system that conforms a set of standards enabling software developers to deploy software applications for the platform.

NoSQL Database: Modern databases conceived for web applications. Unlike a relational database, a NoSQL database does not store data and relationships in tables. Conversely, NoSQL databases are schema-free, distributed and horizontally scalable to clusters of machines i.e. the database is partitioned in a cluster of distributed database servers (each maintaining its own data

and a self-contained schema) and it makes easy to add or remove, namely to scale, a single database server.

RESTful Services: In a distributed computing environment, the Representational State Transfer (REST) architecture allows clients and servers to interoperate by using a standardized interface and protocol using a uniform set of simple and well-defined operations. Resources are manipulated using a fixed set of four create, read, update, delete operations: RESTful web service exposes a set of resources identified by URIs and manipulated using a fixed set of four operations (i.e. create, read, update, delete).

Web Service: A Web Service allows two resources to communicating each other over a network Internet for transferring machine readable file formats such as XML and JSON in a manner prescribed by its interface.

Web 2.0: A recent new vision of the Web that enhances collaboration and interaction of users with each other. Unlike traditional Web sites where users had a passive role in viewing information, Web 2.0 environments (such as social networks sites, blogs, wikis etc.) are grounded on user-generated content and foster people to social media dialogue.

GWAS as the Detective to Find Genetic Contribution in Diseases

Simanti Bhattacharya

University of Kalyani, India

Amit Das

University of Kalyani, India

INTRODUCTION

In the era of unprecedented advancement in medical and technological sciences, Garrod A.E., a physician to the Hospital of Sick Children, in the year of 1902, reported a case of alkaptonuria that he described as “not the manifestation of disease but is rather of the nature of an alternative course of metabolism...”. That was the first report where the possibility of underlying “molecular evidence” behind human disease came in the lime light. Human diseases and their genetic contribution share a complex and intricate relationship, yet to be explored fully. For few cases, phenotypes (diseased condition) could directly be associated with gene, experimentally, whereas a large number of genetic associations behind disease state remained hidden.

That called for a situation where mapping of gene knowledge between afflicted and un-afflicted individuals can be mapped to find out the difference at each point (each nucleotide position or *allele* or *variant*) and the number of occurrences of the mismatched alleles in the diseased individuals (*allelic frequency*) with an assumption that if any allele has higher frequency to appear in the diseased individual then that is associated with the diseased trait. That can be translated as ‘scan through entire gene’ for gene to disease relation mapping or rather, as genetic language, *Genome Wide Association Study (GWA or GWAS)*.

These GWAS data not only provide us with the information on the disease association with

the gene level knowledge but also enable a deeper understanding of the entire scenario generating a landscape of gene with its minute changes that can be extrapolated to genes coding (impact on protein production) or non-coding regions (impact on protein production regulation), the transcription factor binding sites (regulating transcription), epigenetic modification probabilities (regulation in genetic coding), pathways involved (visualizing the upstream or downstream possible effects) extending to heritability of the diseases. These all impose final impact on the phenotype which is nothing but the diseased state to us. Thus, insight generated with GWAS leads us to understand the actual reason or mechanism behind disease onset that, in turn, guides scientists to find novel drug-gable targets for more efficient medications or some times, to look for personalized medications (Bush & Moore, 2012).

With the completion of Human Genome Project (human DNA sequence) in 2003 (International HapMap Consortium, 2003) and the International Hapmap project (haplotype map of the human genome) in 2005, scientists are well-equipped with resources to correlate genetic contribution to disease onset. Success of the GWAS reflects in identifying the genetic factor contributing to Parkinson’s disease, Crohn’s disease, type 2 diabetes and obesity to name a few. These GWAS data can also be accessed through various repositories. However, its smaller variant size, unavailability of replicated reports, smaller population size under study stand as limiting factors to uncover a larger

portion of genetic information to understand properly. With the rapid advancement in research, these limitations will be overcome to generate a better understanding of the entire scenario of disease with GWAS concept.

BACKGROUND

Life material nucleus i.e. DNA is composed of four basic entities and they are: the purines: Adenine (A), Guanine (G) and the pyrimidines: Cytosine and Thymine (T) arranged in a specific pattern that carries information of life. DNA is double helical element where these purines and pyrimidines pair up with each other (A with T and C with G). The complex of different DNA stabilizing and regulatory molecules (protein, RNA etc) along with DNA is collectively known as Genome. Since not only the presence of these basic entities but also their relative position is crucial to maintain the information for life and its sustainability, small variation of these elements (mutation or polymorphism or SNPs) at any of the otherwise conserved position on DNA has been found to bring change in the system. In Pre-GWAS (Ertekin-Taner, 2010) era researchers managed to characterize the genetic association behind disease that followed a Mendelian pattern of inheritance that largely depended on generation wise co-segregation of causal variants with marker alleles that simply followed Hardy-Weinberg Equilibrium. Cause to genetic variation was thought to be chromosomal cross over at chiasmata during meiosis. To explain, suppose, a family or rather a pedigree of a population was studied for a disease that was found to be occurring due to certain enzyme mutation. This, at that time, was considered to be the candidate gene and was followed by characterization, identification of mutated allele as well as developing therapeutics against it. But there could be number of possible reason behind genetic variation within or among the population, random mutations being the ultimate source of genetic variations. Along with that not only inheritance but also other ef-

fects including environment, living style, age etc contribute significantly to genetic changes. And these also can contribute to disease state if the changed allele gets a higher frequency in diseased population than in healthy population. But during GWAS era scientists actually received the scanned report of entire genome that help understanding the complex relation of DNA level mutation and disease phenotypes. As for human cases, each disease may require looking at hundreds or thousands of positions to identify SNPs and associated genes that may contribute to risk of developing a certain disease. Increasing evidences show that GWAS represents a really powerful technique to identify these marker alleles at relatively higher speed and precision. GWAS is based on linkage disequilibrium (LD) principle where loci that are physically close together show stronger LD than the loci that are far apart (Visscher, Brown, McCarthy, & Yang, 2012). The strength of LD for an effective population size also decides the number of genetic marker required to specify the haplotype. GWAS also hypothesizes the 'allelic frequency' of a rare variant will be in low LD with nearby common variant. As time advanced, GWAS started exploring different type of variations and linkage to disease for example rare variant identification through evolutionary model, copy number variation (CNV) that include deletion and/or duplication of DNA segments of diverse size and frequency.

WORKFLOW FOR GWAS METHODS

For any experiment to be successful, a well-structured experimental design is essential. GWAS is not exceptional in this case. It systematically follows basic steps (Figure 1), given below:

- **Sample Collection:** A large cohort collection (>1000) for case and control is essential for initial set up. Chip based microarray technology that assays 1 million or more SNPs from population under study

Table 1. Overview of technologies (including their respective advantages and disadvantages) used for GWAS

Sl. No.	Technology	Detectable No. of Markers	Advantages	Disadvantages
1	Whole Genome Sequencing	Around 35million or EXOME sequencing; around 3 billion for whole genome sequencing	Individual sampling data, better comprehensive information including non-coding (even intronic) SNPs	Selective applications, high cost and analytically challenging
2	Hap-Map genotyping	Hundreds of Thousands	High quality, cost effective, strong statistical association with diseases/phenotypes	Chance of missing uncommon variants
3	RNASeq	Varies with samples and study designs	Detection RNA specific SNPs (both coding and non-coding), variations across expression levels can also be co-related	Dominance of common RNAs.
4	1000 genomes based platforms	Millions	Systemic assessment of all variants including uncommon ones	Require multiple testing, accuracy of genotypic and sensitivity of statistical tests are often compromised to some extent

are the crude source for GWAS sample size for measuring SNP variation. The technology, briefly, explores the hybridization property of DNA with the collection of microscopic DNA spot attached to solid surface. It is also important to know the sample in details. Primarily there are two types of phenotypes: case/control pair (dichotomous; where the genetic variation has to be deciphered by comparing, like schizophrenia related SNPs) and quantitative traits (where the phenotype is measurable like blood group). Based on the sample type the source platform is selected and derived data is further taken for analysis. In this regard, quality control step for the data is very crucial to start with a good set of samples. GWAS files contain vast amount of data and thus are prone to error. Again different methods are adopted while generating the data by different cohorts which increase noise to signal ratio. To improve the quality of data and compatibility among cohorts it is necessary to have quality check for the sample that removes false positive cases(Psychiatric GWAS Consortium Coordinating Committee et

al., 2009). Table 1 provides as short description of different technologies used for collecting data for GWAS. Advantages and limitations of each technique are also discussed.

- **Find Deviating SNP:** From expecting haplotypes visualize SNP-SNP interaction with HapMap: Chip derived hybridized sample DNA then is extracted and the haploid is taken for sequencing. The result of sequencing experiment is then mapped to the known or control DNA sequence. Thereby the mismatched portion, considered as variant, is obtained. The SNP to SNP interaction is further identified with HapMap result. Other than HapMap, global view of all SNPs signals can also be represented via Manhattan plots. Advantage of this plot is that the strengths and location of each SNP can be directly derived (Figure2). However unlike HapMap, correlation between two or more SNPs and associated phenotype cannot be derived from such plot.
- **Detection of Potential Association Signals:** Once the deviating SNPs are gathered, statistical analysis is carried out

to detect the association of the variant to the disease phenotype and majorly done by examining single SNP for its association, done with a series of single locus statistics test. Generalized linear model (GLM) is generally approached to test for qualitative traits and GLM is linear regression model that broadly applies Analysis of Variance (ANOVA)(Hong & Park, 2012). The assumptions are: 1) normal distribution of variance, 2) the trait variances within each group are same and 3) the groups are independent. On the contrary, case/control traits are analyzed with contingency table or logistic regression followed by chi-squared test or related Fisher's exact test. The statistical power derived from these will direct the strength of true association in each case. This is further then stratified based on allelic association or Genotype association followed by further grouping into dominant, recessive, additive or multiplicative type.

- **Fine Mapping:** This step requires all variants in the associated region to have been imputed in genotype or associated version through quality check with stringent conditions and large sample size that is sufficient to resolve among highly correlated signals. The methods employed here broadly calculate posterior probability that tells whether the variant in that locus is causal. Suppose an allele A in the SNP is found to be changed to G through GWAS experiment and found to have high LD with nearby SNP. Now it also requires the SNP location (whether intergenic, within the gene or at nearby location of genes), gene information, allelic change position, consequences etc to know in details about the SNP.
- **Replication of Detected Association in New Cohort or Subset for Validation Purpose:** Once an associated and finely mapped variant with correlated data comes

up, the study is replicated through the new cohort keeping the condition same or through the subset of the sample taken. This step essentially examines the robustness of the experiment design and its outcome.

- **Biological or Clinical Validation:** However, statistical power calculations or significance analyses will only predict the effect of variant (whether risk or protective). To make the findings be free from doubts these findings are validated with biological experiments or clinical validations.
- **Downstream Analysis and Functional Annotations:** The association is further expanded with meta analysis to understand the integrated knowledge of SNP-disease association and consequences (Evangelou & Ioannidis, 2013) for instances, quantitative trait loci analysis, gene ontology or pathway enrichment etc.

IMPORTANCE OF GWAS

In the pre-GWAS era, studies required to go from phenotype (i.e. understand the disease/trait first) to biological processes (with which the disease/trait is mostly associate) so that the causing agents (mostly the genes in the pathway) could be identified. Further molecular dissection, mutagenesis studies and other analyses were carried out to characterize the identified gene and the marker. If the assumption would have been 'one gene one disease' then it would have one shot identification process but could not be held true for complex gene-phenotype relationships. GWAS has this selective advantage for which prior knowledge on biological pathway of the trait does not have to be known as it approaches SNP level to gene to phenotype direction. Since GWAS does an in depth study at allelic level often it comes up with novel candidate genes. The independent statistical analysis and power driven association result often

Figure 1. Overview of GWAS experiment design. This is a schematic representation of GWAS data collection and further downstream analyses. The initial sample cohort should be at equal state ideally. Test set may contain heterozygous allele (shown in yellow). SNP are collected and deviated markers are statistically validated and functionally mapped.

Figure 2. Sample of Manhattan plot based visualization of GWAS data. In a Manhattan plot, x-axis denotes to location of a SNP while the y-axis denotes the strengths of association ($-\log_{10}$ of pvalue). Highly probable SNPs often have strong values associated in the y-axis (marked in green). One major limitation of such visualization is that such plots do not provide any correlations among SNPs and phenotype of interest. The plot is created with the R qqman package.

Source: Turner, 2014

eliminates the chance of biased specific association of SNP to phenotype. Its efficacy in finding SNP and CNV provides more robust data as well as gives information on heritability or ancestry of each subject. Furthermore, GWAS generated huge data to analysis and not only association or fine mapping the post GWAS requires a string meta analysis where more information on SNP/gene correlated data like amino acid change, protein motif change, alteration in biological processes/pathways etc. To access these information effective collaboration are formed with strong consortium of expertise and finally an integrated answer to disease mechanism is solved.

GWAS FOR NEW TARGET IDENTIFICATION IN DISEASES

With GWAS personalized medicine (Thrall J.H., 2004) has achieved a new edge. Personalized medicine is referred to tailoring of medical treatment to the individual characteristics of each patient. In pre-GWAS era the most acclaimed belief was for the association of 'one gene one disease' and identifying the causal gene required 'trial-and-error' kind of studies. But with the advancement in understanding disease complexity a new insight has been revealed showing multiple genetic association and SNP variation behind disease onset. Even within a population under study, there exists SNP level differentiation in closest relatives. This triggers the importance of understanding the disease prospective for each and every individual taken as case and identifying the causal agent behind the disease in order to develop personalized medicine. Personalized medicine relies on traditional as well as newly developed concepts of genetic association with disease and environmental factors regulating it in order to individualize prevention, diagnosis and treatment. GWAS provides insight to this modern age understanding of multiple gene to disease association by performing entire genome wide scanning at each point, thereby scrapping

variant information for individuals (more often called 'personalized genome') along with cohort sample. A classic example is study of medicine trastuzumab which is prescribed for only 30% of the breast cancer patient who carry a rare mutation that causes over-expression of protein HER2.

Not only to find out rare events for personalized medicine, GWAS is an intricate study in different fields of diseases like cancer, autoimmune diseases, central nervous system related disorder and many more to name. GWAS have been implemented in five of the commonest cancer types: breast, prostate, colorectal, lung and melanoma and have successfully identified 20 novel disease loci (Easton & Eeles, 2008). With GWAS the genetic architectures of multiple sclerosis (Bashinskaya, Kulakova, Boyko, Favorov, & Favorova, 2015), schizophrenia, bipolar disorder etc have been investigated and GWAS has successfully identified disease susceptibility, clinical phenotypes and treatment responses. Autoimmune diseases like celiac disease, crohn's disease, rheumatoid arthritis etc occur when own immune cells of an individual attack and destroy body's cells. With GWAS analysis, the number of genetic risk loci associated with different autoimmune diseases has remarkably increased. Similarly GWAS has encroached different disease section and have identified more associated variant for the given disease/trait than was known before.

GWAS AND ITS SPECIFICITY

First GWAS Discovery

The first report that included prominent GWAS involvement came into light in 2005 when Klein R.J. *et al.* were studying Age Related Macular Degeneration (AMD), a major cause of blindness in elderly. They performed genome wide screening of 96 cases and 50 controls for identifying polymorphisms associated with AMD. Their statistical analysis showed, among 116,204 SNPs that were screened one variant in the complement factor H

(*CFH*) gene showed strangest correlation (p value $<10^{-7}$) with the diseased state. Further resequencing revealed a variant in linkage disequilibrium with the risk allele representing a tyrosine to histidine change at amino acid 402 which is interestingly at the binding site for C-reactive protein (CRP) and heparin. Moreover, *CFH* is located in a region of chromosome 1 that is repeatedly linked to AMD in family based studies. Previous studies on the conservation of tyrosine at 402 for the functionality of *CFH* were reported along with the report for elevated serum CRP during AMD. These previous reports and Klein group's finding established a mechanism of AMD onset through GWAS (Klein, Zeiss, Chew, & Tsai, 2005).

One Article Retraction Due to Statistical Anomaly

Statistical analysis plays a crucial and strong role in GWAS data analysis. Anomaly in this aspect can cause severe case of false positive data as inference. Such a case happened when Sebastiani et al. presented their work on identifying sets of markers responsible for aging (Sebastiani et al., 2011). Although they collected samples from more than 1000 centenarians, they employed a statistical analysis that was different from the canonical process and led to controversy in scientist community regarding data discrepancies. Ultimately they had to retract their article, one year after its publication.

LIMITATIONS

GWAS is critically dependent on the samples and control taken for studies. Thus GWAS involves different limitations associated with proper quality control and study setup. Common problems that usually occur during GWAS involve case-control groups with less defined demarcations, smaller and less diversified population under study, erroneous sample stratification and proper control size that is comparable to test set for multiple testing.

GWAS depends on the statistical relevance that an SNP is linked with disease/trait for a population compared to control population. An error in sample collection, study design and proper quality control will definitely fall into results with faulty statistical report. This will then give rise to a situation of false positive or false negative data and thereby over or under representation of SNP-gene relation. Furthermore, most of the time scientists falsely assume that GWAS SNP gives the hint for the causation of the associated disease but the real scenario is GWAS states the possibility of correlation between an SNP and disease. A sample size with proper statistical power is essential for success of GWA study. Sometimes improper statistical analysis may give false negative result. However, the above mentioned issues can be taken care of and can be corrected. But there are certain fundamental problems associated with GWAS like the common belief of heritability of SNPs for specific disease/traits. To avoid such cases the experiment needs proper information of sample as well as linkage analysis with relevant statistical measures. GWAS detects only those variants that are common ($>5\%$) in a population. Validation of results requires replication in independent samples from different population to avoid any falsified data. Furthermore stringent statistical power calculation may give rise to over or under representation of association. Most of the time the SNPs do not fall in the protein coding region or at least at the nearby region of protein coding gene with known functionality. These sets of SNPs are often under analyzed though they may have significant effect on phenotype.

FUTURE DIRECTIONS

The pre-GWAS era thought of one gene - one disease but with the intervention of GWAS, scientific community has been forced to reprocess their thoughts towards complexities of SNP to disease relation. This has huge impact on human genetics. This view has been further strengthened

due to the parallel increase in Whole Genome Sequencing data. With the rapid progress of associated technologies, new and cheap sequencing techniques will continue to evolve further and that will generate huge sample set for careful and thorough fine-mapping. A major concern regarding GWAS is complex dependence-structure for SNPs as well as for individual sample. Mixed model approaches are now being adopted that provide a general and flexible attempt to carry out GWAS of correlated phenotypes.

In the near future, following areas of research or healthcare could benefit significantly from the technical and translational development of GWAS or its associated techniques:

- **Personalized Medicine:** This is going to be area where GWAS will probably have maximum impact. Armed with only gene sequence information, GWAS plots (hap-map and Manhattan plots) provide some sort of systemic view of a person's overall genetic architecture. This type of information will help researchers and physicians in finding effective medicines for each and every patient. Drug like trastuzumab already has already shown the way.
- **Phenotype Refinement or Re-Classifications:** What gene signatures differentiate Crohn's disease from ulcerative colitis or psoriasis from lupus? While there are several genes and signaling pathways that are significantly overlapping across such diseases, GWAS has the potential to provide a clear set of gene signatures that would help in proper classification of phenotypes (re-classification in some cases).
- **Understanding the Impact of SNPs in the Non-Coding DNA:** Majority of human DNA is non-coding. However GWAS has found several SNPs which are strongly associated with several diseases are located in non-coding region. Understanding the impact of these non-coding SNPs and finding ways to translate that information to

advancement of healthcare could be major focus of GWAS studies.

- **Predictive Analysis Based on Genome Profiling:** Similar to personalized medicine, GWAS helps in identifying potential disease threats for a particular individual. The advantages of hap-map and Manhattan plots (Figure 2) are that they help in weighing the potential impact of known disease causing mutations by directly comparing each person's co-occurring mutations with that of a population data.
- **Policy-Making:** This could be a little distant reality but definitely a very important one in the long run. Similar to many scientific discoveries, GWAS information can also be used for un-explained exploitation of potential threats. While a person may be predicted to be susceptible to certain diseases based on the genetic makeup but there also lies a chance that the person might never develop those diseases at all. To stop healthcare providers from unnecessarily punishing a person due to predicted threats, proper guidelines have to be brought in place.

WEBLINKS

There are several tools/web-servers and statistical packages available for GWAS analysis and further fine mapping. For each of the type of experimental design and analysis selected set of examples are given in Table 2.

CONCLUSION

Today GWAS, along with HapMap project data, other sequencing data, various statistical analysis and further annotations has become a powerful tool to analyze variant association with diseases/traits with the extension in gaining deeper knowledge in disease mechanism for producing personal-

Table 2. List of Web-tools used in GWAS

ized medicines. A careful selection of samples and clever experimental design would make it a powerful tool to identify new targets for better understanding of complex diseases. Its efficacy in pedigree wise and expression dependent analysis of genetic association with diseased phenotype has made it an essential tool for decoding developmental abnormalities across several generations of a population. However, GWAS gives least information for SNPs situated in the non-coding portion (intergenic, distant from known protein coding gene region) of DNA and thereby GWAS loses a large amount of data for downstream analysis. With the advancement in science in near future this problem will definitely get its solution and GWAS will be fully explored to get answers for disease complexity.

KEY TERMS AND DEFINITIONS

Chromosome: A chromosome is a packaged and organized structure containing most of the DNA of a living organism.

Gene: Gene has different definitions depending on the way it is studied in biology. As per classical (Mendelian) genetics a gene is the basic physical and functional unit of heredity. According to molecular biology a gene is a locus (or region) of DNA which is made up of nucleotides and is the molecular unit of heredity.

Genome: Genome refers to the complete set of genes or genetic material present in a cell or organism.

Linkage Disequilibrium: Linkage disequilibrium is the non-random association of alleles at different loci in chromosome.

Locus: A locus (plural loci), in genetics, is the specific location or position of a gene's DNA sequence, on a chromosome.

Nucleus: A nucleus is a membrane bound cellular organelle that contains genetic material in eukaryotes.

Regression Analysis: A regression analysis is a statistical process for estimating the relationships among variables.

SNPs: Single nucleotide polymorphism (SNP) s are single base pair changes in the DNA sequence that occurs with high frequency in human genome.

RNA Interference Therapeutics and Human Diseases

B**Dolly Sharma***PEC University of Technology, India***Shailendra Singh***PEC University of Technology, India***Trilok Chand***PEC University of Technology, India*

INTRODUCTION

Humans have more than 20 thousand genes that are protein coding. Proteins are essential building blocks of our body as they perform a variety of functions in human body (Pines, 2007). They produce hormones, enzymes and hemoglobin (Hoffman & Falvo, 2004). As proteins are important, their accurate production is also essential. Diseases are caused either by formation of defective protein or by over production of protein or less production of protein (Shenoy, & Jayaram, 2010; Selkoe, 2003). Diseases like Alzheimer's and Parkinson's disease, Huntington's disease, Creutzfeldt–Jakob disease, cystic fibrosis, Gaucher's disease, Uremia as well as other neurodegenerative disorders, heart disease, some cancers, stroke (Chaudhuri & Paul, 2006) are caused by inappropriate synthesis of protein. Proteins in association with RNA form Ribonucleoprotein (RNP) which relates to diseases like influenza A virus, inherited motor neuron disease spinal muscular atrophy (SMA) (Pellizzoni, 2007), premature aging, cancer (Blasco, 2005), aplastic anemia (Yamaguchi, Calado, Ly, Kajigaya, Baerlocher & Chanock, 2005), Alzheimer (Diner, Hales, Rabenold, Bishof & Duong, 2004) etc. In short, RNA and protein is linked with an outsized figure of diseases.

As gene expression (Alberts et al., 2007) is the process of formation of proteins, wherein DNA

acts as a template for mRNA which further gets converted into proteins. So, altering the gene expression process may prevent from some disease to occur. More precisely, it is altering gene coding at mRNA level. This is the concept adapted by RNA Interference Therapeutics. RNAi Therapeutics (Aagaard & Rossi, 2007) is the branch of science that focuses on control of gene activity at RNA level to cure diseases.

This chapter is organized as follows: RNA, DNA and gene expression are discussed in Introduction and Background section followed by RNA types, RNA interference process and RNA Therapeutics. Table 1 mentions some of the RNA Therapeutics companies. Further RNAi Therapeutics techniques PMO, LUNAR, RNA upregulation and Gene Silencing are discussed. It is concluded by RNAi Therapeutics' challenges and issues and lastly its future research directions.

BACKGROUND

Cells are the building blocks of life. Inside nucleus of a cell, DNA and RNA molecules reside. Ribonucleic Acid (RNA) molecule is a single stranded sequence consisting of four bases Adenine (A), Guanine (G), Cytosine (C) and Uracil (U). This single stranded sequence is known as the primary structure of RNA (Tinoco & Bustamante, 1999).

The backbone of RNA contains ribose as sugar. Phosphate groups are also attached to ribose. RNA can be synthesized from DNA. DNA is another molecule which is double stranded molecule. DNA consists of nucleotides that contain a phosphate group, a sugar group and a nitrogen base. Nitrogen bases are Adenine (A), Guanine (G), Cytosine (C) and Thymine (T).

DNA molecule contains a number of genes. Some genes code for protein and others do not. The process of production of protein is called gene expression. Precisely, Gene Expression process involves two sub processes- Transcription and Translation. Gene expression process is initiated by making a copy of DNA to produce a complementary strand called messenger RNA (mRNA) (Anfinsen, 1972) as shown in Figure 1. mRNA is one of the types of RNA. Thymine of DNA is replaced by Uracil of RNA. This step is called Transcription. Proteins are made up of sequence of amino acids. 20 amino acids exist. The bases of mRNA in sets of three, code for a specific amino acid and forms a codon as shown in Figure 1. As the number of bases is four, so 64 ($4 \times 4 \times 4$) possible codons are there. Consequently, more than one codon may code for a specific amino acid. The amino acid is meshed together with codon by another type of RNA which is transfer RNA (tRNA). tRNA contains a complementary sequence of bases on the other side called anti codon as shown in Figure 1. A sequence of amino acids is called a protein. This process is called Translation. Together these processes transcription and translation are termed as gene expression. Each protein consists of a unique sequence of amino acids. Ribosomal RNA (rRNA) links the amino acids so that specific protein is formed.

TYPES OF RNA

Gene Expression is catalyzed by majorly three types of RNAs, namely, messenger RNA, transfer RNA and ribosomal RNA.

- **Messenger RNA (mRNA):** mRNA is responsible for transfer of genetic information from DNA to the ribosome and is the biggest family of RNA molecules. The structure of mRNA is shown in Figure 2.
- **Transfer RNA (tRNA):** Suppose we need to bake a cake. We need a kitchen, a recipe and raw materials. In the gene expression process, kitchen correlates to the cell, recipe is with mRNA and raw materials are supplied by tRNA. It brings together RNA nucleotides and amino acids.
- **Ribosomal RNA (rRNA):** rRNA links the amino acids into specific sequence for translation into particular protein.

Other types of RNA are non-coding RNA, transfer-messenger RNA, small-nuclear RNA, micro RNA, small interfering RNA, small nucleolar RNA, antisense RNA and Signal recognition particle RNA. The details of these types are out of the scope of this chapter. Additional readings section can be referred for the same.

RNA INTERFERENCE

Decades ago, an experiment was conducted to increase the color of petunias flower wherein color producing gene was injected to the flower. Instead of increase in color, it was observed that color was lightened and even white petunias were produced in generations of flower (Jorgensen, Cluster, English, Que & Napoli, 1996). This was how the concept of gene expression suppression was coined. Further experiments revealed that introduction of sense and antisense RNA together forming double stranded RNA (dsRNA) leads to gene silencing (Fire et al., 1998).

The mechanism of RNA Interference (RNAi) involves treating the disease causing gene with specific small interfering RNA (siRNA) that targets the specific messenger RNA (mRNA). This mRNA is involved in production of protein that leads to the disease in question. The motive

Figure 1. Gene expression process

Figure 2. tRNA, mRNA and rRNA

of treating this mRNA with siRNA is to degrade the mRNA and thus prevent the formation of protein causing disease (Figure 3). Alteration in protein production refers to impeding the gene expression process. This concept of RNAi leads to Gene silencing that means switching off the target gene. It prevents the expression of a certain gene. One of the applications of Gene Silencing technique was to cure Huntington disease which was caused by the production of protein called Huntington (Sah & Aronin, 2011).

RNA based medicines have been in focus since many years. RNA Therapeutics drug are designed to increase or decrease the production of a protein involved in a disease. It is a mechanism to regulate normal gene expression in order to eradicate several disorders like cancer, Hepatitis C, Huntington's Disease, HIV, malaria etc. (Abdolhamid et al.,2010). Some of the Therapeutics companies have been discussed in Table 1.

PMOs Based RNA Therapeutics

PMO stands for phosphorodiamidate morpholino oligomer. These are synthetic RNA's consisting of same bases as of RNA (A, C, G and T). They

are molecular structures that are binded to RNA at specific position in order to change the function of RNA. As they have reasonable RNA binding affinity and low protein binding affinity, they bind RNA wholly without off- target effects. Their prime function is to retard the gene expression in order to prevent cells from making a targeted protein and thus preventing the disease to occur.

PMO's are especially stable, highly soluble and non-toxic. They have the following functions: (Moulton, 2013) blocking translation of mRNA (Hudziak, Summerton, Weller & Iversen, 2000), modifying of splicing of pre-mRNA (Alter et al.,2006), blocking miRNA maturation and activity (Kloosterman, Lagendijk, Ketting, Moulton, & Plasterk, 2007), and blocking other RNA sites – splice regulation sequences (Bruno, Jin & Cote,2004) and ribozymes (Yen et al., 2004).

The manufacture of medicine using PMO technology drives through a number of steps. After examining the target RNA, subunits of PMOs are created by converting 5 sided RNA rings to 6 sided PMO subunits. Then these are linked to form the final structure. This structure corresponds to the targeted RNA. Figure 4 has been adapted from Sarepta Therapeutics.

Figure 3. RNAi process

Figure 4. PMO's technology

Duchenne muscular dystrophy (DMD) was treated with PMO's Technology. This disease is caused by mutations that disrupt the reading frame of the human DMD gene. Selective removal of exons flanking an out-of-frame DMD mutation can result in an in-frame mRNA transcript that

may be translated into an internally deleted, Becker muscular dystrophy (BMD)-like, but functionally active dystrophin protein with therapeutic activity (Poppewell, Graham, Malerba & Dickson, 2011).

PMO are RNA based molecules in which morpholine ring replaces the ribose. PMOs are also

used for restoration of dystrophin in humans which protects from muscle fiber injury (Kinali et al., 2009) as strengthening of muscles depends on it.

Huntington's disease (HD) is a progressive brain disorder genetically transferred disease that hits a person's cognitive, emotional behavior and leads to uncontrolled jerky movements in body. Mutations in HTT gene cause HD. A trinucleotide sequence CAG of DNA sequence repeats itself 20-30% times leading to HD. PMO's have been used to suppress mutant huntingtin expression (Sun et al., 2014; Burgess, 2014).

Behavior of Flavivirus has also been studied using PMO's. Flavivirus is a genus of viruses in the family Flaviviridae. This genus includes the West Nile virus, dengue virus, tick-borne encephalitis virus and yellow fever virus (Brinton & Disputo, 1988). Viruses like West Nile virus (Deas et al., 2007), Marburg virus, Ebola virus (Warfield et al., 2006), etc are under test while treating them with PMO's. PMO's whose sequences were complementary to RNA elements located in the WNV genome included various sub structures like stem loops, Pseudoknot (Sharma, Singh & Chand, 2014; Sharma, Singh & Chand, 2015; Jiwan & Singh, 2012a; Jiwan & Singh, 2012b; Mann, & Singh, 2011) etc.

LUNAR Technology Based RNA Therapeutics

LUNAR stands for Lipid-enabled and Unlocked Nucleic Acid modified RNA delivery technology. In this technique, lipid particle is fused into the cell membrane that leads to biodegradation process and delivers the required RNA. Arcturus Therapeutics, Inc. ("Arcturus Therapeutics", 2015), a leading company in RNA therapies for rare diseases works on this technology.

Cystic Fibrosis (Hegarty et al., 2009) is a genetic disease that affects the lungs and digestive system. Cystic Fibrosis is being treated with the help of LUNAR technology. Researchers at Arcturus Therapeutics tried injecting human erythropoietin messenger RNA (mRNA) into non-human

primates using LUNAR technology. The results were outstanding. The chemically modified RNA was well absorbed by the primate and protein expression proceeded as expected. Most important there were no off target effects of the activity.

Both siRNA and mRNA are used with LUNAR technology. Similar to LUNAR-formulated cystic fibrosis transmembrane conductance regulator (CFTR) mRNA, LUNAR-formulated thrombopoietin (TPO) mRNA, LUNAR-formulated ornithine transcarbamylase (OTC) mRNA and LUNAR-formulated hepcidin (HPN) mRNA have been geared up. LUNAR-formulated TPO mRNA is used for the treatment of thrombocytopenia which is a blood related disorder that leads to low platelet count. LUNAR-formulated ornithine transcarbamylase (OTC) mRNA is used for the treatment of ornithine transcarbamylase deficiency, which leads to accumulation of ammonia in blood. LUNAR-formulated hepcidin mRNA is used for the treatment of iron disorders.

Arcturus Therapeutics ("Arcturus Therapeutics", 2015) has rightly proved that mRNA medicines have brought a revolution. It has become possible to target any gene in the human genome (Nassa, Singh & Goel, 2013). Various gene prioritization techniques (Gill, Singh, & Aseri, 2014), gene prediction techniques (Goel, Singh & Aseri, 2013a; Goel, Singh & Aseri, 2013b) and gene regulatory networks (Singh, 2013a; Singh, 2013b) are used to identify candidate genes for a particular disease. Not only in humans, genetic testing can be conducted even in unborn babies to detect diseases (Singh, & Singh, 2011).

Therapeutics for RNA Upregulation Using Long Non-Coding RNA

Few years back non-coding RNA was recognized as responsible for several regulatory functions in body. Long non-coding RNA has a specific effect on gene regulation. Using this concept, RNA can be targeted to selectively 'activate' therapeutic protein expression (Lee, 2012). Till now in this chapter, we have discussed the evolution of RNA

therapeutics for controlling gene expression, but now we would discuss the same for up-regulating the gene expression (Donner, 2014). Some genes including tumor suppressors, growth factors, transcription factors and genes that are deficient in various genetic diseases require upregulation (Wahlestedt, 2013).

During cancer, some tumor suppressor genes are inhibited. These genes encode protein that hinders the formation of tumors. Mutations in the said gene inhibit the function of tumor suppressor gene, thereby leading to growth of infected tissues. A two-hit mutation process (Hyland, 2008) is shown in Figure 5 that results in tumor.

In cardiovascular diseases, therapeutic genes are upregulated using Long non-coding RNA like APOA1-AS and human mimics of Bvht (Fatemi, Velmeshev & Faghihi, 2014). Similarly neurological disorders occur due to downregulation of a protein called Brain-derived neurotrophic factor (BDNF). BDNF is a therapeutic target for neurological disorders. As LncRNA has the potential to target specific set of genes, it has been a major therapeutic target for upregulation.

Not only lncRNA but short activating RNA has also been used for upregulation. Mina Therapeutics proposed a novel approach for treating diabetes (Reebye et al., 2013). Diabetic patients who are bound to inject insulin supplements in their body may be treated with the said approach. In this approach, short activating RNA is used to produce insulin in body using surrogate cells by upregulating several pancreatic endodermal genes.

Antisense RNA Based Gene Silencing

Antisense RNA (asRNA) is RNA having molecular sequence which is complementary to a specific mRNA. Thus asRNA can be binded to mRNA thus forming a double stranded RNA just like DNA. This double stranded RNA can inhibit gene expression. There are various sources of asRNA including induction by doctors. Gene silencing component is produced using asRNA which then interacts with mRNA for its degradation. This process finally alters the gene expression thereby curing the disease. Such small molecules (gene silencing components) have been synthesized to cure many diseases like Myotonic Dystrophy Type 1 and Myotonic Dystrophy Type 2.

Neuromuscular diseases like DMD, myotonic dystrophy and spinal muscular atrophy (SMA) are also treated using antisense oligonucleotides (Muntoni, & Wood, 2011). Myotonic Dystrophy occurs due to repetition of some units in non coding elements of mRNA. More the number of repetitions, severe is the disease. Spinal muscular atrophy (SMA) is another genetic disease affecting nervous system that controls muscle movement. SMA occurs due to deficiency of SMN, a motor neuron protein. Antisense oligonucleotides have been designed to modulate pre-mRNA splicing for restoration of functional proteins in body.

Not only antisense oligonucleotides, but double stranded RNA (dsRNA) that is homologous to the target gene is also used for gene silencing. In

Figure 5. Two hit mutation for retinoblastoma

Figure 6. Antisense RNAi based gene silencing

this technique dsRNA is diced to produce siRNA (Wood, Trülzsch, Abdelgany, & Beeson, 2003). The antisense strand of siRNA, being complementary to mRNA, leads to mRNA cleavage, degradation and hence gene silencing as shown in Figure 6.

RNAi THERAPEUTICS: CHALLENGES AND ISSUES

RNAi Therapeutics is not easy to implement. Also there are certain issues (Ebbesen, Jensen, Andersen & Pedersen, 2008; Burnett & Rossi, 2012) involved such as:

- Induction of drug into the specific body part,
- Distribution of drug into cells,
- Successful silencing of gene,
- Side Effects of drug on other genes,
- Generate natural immune response,
- Instability under physiological conditions.

Biodistribution of RNAi drugs includes technical and scientific challenges including extended blood circulation times, vascular escape, tissue penetration, cellular uptake, and escape into the cytoplasm (Haussecker, 2014). First and foremost question is how to deliver the drug to the body. Some of the techniques are nanoparticles, cationic lipids, antibodies, cholesterol, aptamers, viral vectors GalNAc-siRNA conjugates and Dynamic PolyConjugates/DPCs (Aagaard, & Rossi, 2007). Two strategies may be adopted- in vivo delivery

or ex vivo delivery. In vivo delivery refers to concept of delivering the said drug to the body itself through inhaler or direct injection. On the contrary, ex vivo is a concept of extracting cell from patients, modify them in environment external of body and re-inject the modified cell back to the body. Both the techniques have their own challenges (Tiemann & Rossi, 2009).

Another issue of RNAi delivery is that RNA molecule has to reach cytoplasm of cell in order to interact with protein and hence carry forward the process of gene silencing. For example, in case of cancer therapy, when siRNA routes through the blood, it is easily digested by nucleases in the serum thereby leading to its degradation instead of following its targeted action.

Off target effect is another problem. A gene which is closely related to the targeted gene is also damaged. This leads to unwanted action in body. The literature shows masses of consequences of experiments conducted so far for off-target effects of RNAi delivery. In some cases physiological effects have lead to non-targeted gene expression (Jackson et al., 2003) and even alteration of gene expression of many non-targeted transcripts.

Another growing concern while inducing RNAi in vivo is the activation of immune response. This even sometimes leads to interferon effect. Interferons (Andrea, Gariglio, Gioia, Gariglio & Landolf, 2002) are actually signaling proteins that are sent by cells to other cells signaling them to increase their immune effect. So, the immunostimulatory “side effects” must be taken in account when inducing RNAi.

FUTURE RESEARCH DIRECTIONS

RNAi Therapeutics has been improving incessantly since a decade. Although there are some hurdles to be able to traverse clinical barrier easily, particularly RNA delivery. Lots of lessons have been learnt from previous trials. These lessons are unquestionably going to aid researchers and scientists to accomplish their goal to conquer fatal diseases. With awareness of the topics of gene expression, artificial RNA, techniques for RNA Therapeutics like PMO, Lunar based approach, antisense RNA etc, a number of researchers can bring revolution in disease control. Firstly, research can be carried out on structures of RNA that cause a particular disease. Further research can be done on preparation of synthetic RNA to control that disease. Delivery of drug to cells is another area.

CONCLUSION

As RNA is associated with a large number of human diseases, treatment of these diseases are also related to RNA. The process of Gene expression is the foundation of functionality of human body. Gene expression includes RNA. Controlling the gene expression leads to control of formation of diseases causing structures in nucleotide sequence. Synthetic RNA controls the gene expression and thus there is no doubt regarding the potential of RNAi Therapeutics in treatment of diseases. Novel techniques and delivery systems are expected to be investigated to perk up RNAi delivery. RNAi Therapeutics should be able to treat more number of diseases in near future. It is going to bring revolution in human disease therapy.

KEY TERMS AND DEFINITIONS

dsRNA: dsRNA stands for double stranded RNA. Sense and antisense RNA together form dsRNA.

Gene Expression: It is the process of formation of protein, intermediate steps being conversion from DNA to mRNA.

Gene Silencing: The process of prevention of gene expression process during translation or transcription process is called gene silencing.

LUNAR Technology: LUNAR stands for Lipid-enabled and Unlocked Nucleic Acid modified RNA delivery technology. In this technique, lipid particle is fused into the cell membrane that leads to biodegradation process and delivers the required RNA.

PMO: PMO (phosphorodiamidate morpholino oligomer) are synthetic RNA who retards the gene expression in order to prevent cells from making a targeted protein. They are molecular structures that are binded to RNA at specific position.

RNA Interference: The mechanism of RNA Interference (RNAi) involves treating the disease causing gene with specific small interfering RNA (siRNA) that targets the specific messenger RNA (mRNA).

RNAi Therapeutics: Altering gene coding at mRNA level is called RNAi Therapeutics. RNA Therapeutics drug are designed to increase or decrease the production of a protein involved in a disease.

siRNA: Small interfering RNA is also known as silencing RNA or short interfering RNA. siRNA is formed from double-stranded RNA molecular sequence of length 20-25 base pairs and is used for knockdown of long noncoding RNAs genes.

INTRODUCTION

Physically handicapped people encounter various kinds of obstacles and difficulties in their daily lives due to the restricted ability of motion. Assistive technologies represent a crucial challenge of scientific studies to overcome such an issue of reducing quality of life. Assistive devices such as wheelchairs, orthoses and prostheses are designed and built to contribute rehabilitation progress and to regain lost functions, as well. Although human body parts have intricate forms and functions, artificial devices and components integrating to the body are anticipated to compensate the fundamental functions related to user's demands. Upper or lower arm amputations also result in severe cosmetic matters. However, what is more important and obtrusive is the loss of primary functions including manipulating and grasping the objects besides the locomotor tasks which are performed by human body during daily activity.

BACKGROUND

Development of human arm prosthetics, which are improved to regain lost functions of amputated limbs, encounters critical and challenging problems to carry out various dexterous tasks. To

date, many of revolutionizing design of human arm prosthetics including Boston Arm (Mann & Reimers, 1970), Deka Arm (Resnik, 2010), Otto Bock trans carpal hand (Otto Bock Health Care, Minneapolis, MN), and Shanghai Kesheng Hands (Shanghai Kesheng Prosthese Corporation Ltd.) have been developed. Intuitive and precise control of such prostheses is still one of the main interests of scientific studies. The main deduction from researches could be stated as control of the prosthetics is a particular concern of understanding the nature of the electrical activations of muscles. Imitation of the fundamental patterns of human arm motion depends highly upon the transformation of the neuromuscular activities of residual limbs to a specific control signal for controlling the artificial arm. In this respect, myoelectric signals provide a base of intuitive control, unlike the conventional or direct control. The dexterous control of such myoelectric-based prostheses requires a clear extraction of features from recorded surface electromyography (SEMG) signals and pattern recognition to discriminate the motion and force intentions of the prosthetics users. The progress of feature extraction from SEMG signals has an extensive coverage of myoelectric controlled prostheses studies due to the features in both time and frequency domains have the great potential on representing clear and meaningful information

of EMG signals. Additionally, the feature classifiers have been given a special scientific interest by researchers. Selection and developing of the case-specific classifiers, which are desired to have the optimal performance to specify motion classes, still continue to be the main goal of current studies. Although, various types of classifiers such as linear discriminant analysis (LDA), support vector machine (SVM), artificial neural networks (ANN) and fuzzy logic (FL) techniques have been utilized to classify human arm motion patterns, merits, shortcomings and pitfalls of the classifiers are still required to be discussed extensively.

FUNDAMENTAL ASPECTS OF EMG

EMG is the electrical activity of skeletal muscles (Basmajian & Deluca, 1985). It represents the summation of the muscle action potentials which cause the contraction of muscle fibers. Recorded EMG data by means of electrodes are amplified and filtered to eliminate the motion artifacts, as well as the environment and device related noises. Rejection of ambient influences on natural muscle activation improves the accuracy and usability of EMG signals. One of the most widely usage of EMG signals is to control the myoelectric-based prosthetics which are used by amputated people. Control scheme for EMG-driven human arm prosthetics includes a sequential series of signal processing (Figure 1).

A condensed and clear control signal is needed to control the EMG-based prosthetics. In order to reduce calculation and to provide stability of signal, EMG data are scanned by sliding segmented windows (Figure 2). Because the raw (amplified+pre-processed) EMG signal contains a huge burden of data, this signal is needed to be represented in a concise, but accurate ways. Widely used time domain features extracted from signals includes mean absolute value (MAV), root mean square (RMS), Willison amplitude (WAMP), waveform length (WL), variance of EMG (VAR), simple square integral (SSI), zero crossing (ZC) and integrated EMG (IEMG) (Phinyomark et al., 2013). In frequency domain, mean frequency, median frequency, peak frequency, mean power, total power, and spectral power features are commonly preferred (Phinyomark et al., 2013).

EMG SIGNAL FEATURES

Obtained EMG signals during contraction of a muscle or muscle groups are needed to be quantified in order to relate these signals with some certain sets of movement types (Zecca, Micera, Carrozza, & Dario, 2002). Mathematical expression of EMG signals could be defined using feature extraction approach. An EMG signal could be expressed in two domains including time and frequency domains.

Figure 1. Control scheme of multifunctional human arm prosthetics

Figure 2. The basic representation of sliding windows

Time Domain Features

Features expressed in time domain are useful for pattern recognition process due to no transformation process is required. Easy and fast calculation of features provides to reduce delay which is a critical concern in control of human arm prosthetics. A wide range of time domain features have been proposed by researchers for the purpose of movement or force classification process (Phinyomark, Phukpattaranont, & Limsakul, 2012). While x_k is the k th EMG sample and N is the number of samples in each segment, the most widely used time domain features are given as follows.

Mean Absolute Value

Mean absolute value (MAV) of an EMG signal is the average of absolute value of sequential signal amplitudes. MAV is one of the mostly used features and defined as,

$$MAV = \frac{1}{N} \sum_{k=1}^N |x_k| \quad (1.1)$$

Root Mean Square

Root mean square (RMS) feature represents a calculation of amplitude modulated Gaussian

random process relating to constant force and non-fatiguing contraction. The mathematical expression of the RMS is given as,

$$RMS = \sqrt{\frac{1}{N} \sum_{k=1}^N x_k^2} \quad (1.2)$$

Willison Amplitude

Willison amplitude (WAMP) feature is the number of times the EMG signal amplitude exceeds a predefined threshold. WAMP is an indicator of motor unit action potentials (MUAP) and contraction force in muscles and can be expressed mathematically as,

$$WAMP = \sum_{k=1}^N \left[f(|x_k - x_{k+1}|) \right] \quad (1.3)$$

$$f(x) = \begin{cases} 1, & \text{if } x \geq \text{threshold} \\ 0, & \text{otherwise} \end{cases}$$

Waveform Length (WL)

Waveform length (WL) of EMG signal is the cumulative length of the waveform over the time segment. WL feature can be calculated as,

$$WL = \sum_{k=1}^{N-1} |x_{k+1} - x_k| \quad (1.4)$$

Variance of EMG (VAR)

Variance of EMG (VAR) implies the second-order moment of EMG signal and is a measure of power. VAR feature can be defined as follows,

$$VAR = \frac{1}{N-1} \sum_{k=1}^N x_k^2 \quad (1.5)$$

Simple Square Integral (SSI)

Simple square integral (SSI) of an EMG signal represents the summation of square values of EMG signal amplitude over time segment. SSI can be expressed as,

$$SSI = \sum_{k=1}^N x_k^2 \quad (1.6)$$

Zero Crossing (ZC)

Zero crossing (ZC) feature measures how many times the amplitude of EMG signal crosses zero level. Threshold value is assigned to prevent voltage fluctuations or noises effects. ZC feature calculation could be defined as,

$$ZC = \sum_{k=1}^{N-1} \left[\text{sgn}(x_k \times x_{k+1}) \cap |x_k - x_{k+1}| \geq \text{threshold} \right] \quad (1.7)$$

$$\text{sgn}(x) = \begin{cases} 1, & \text{if } x \geq \text{threshold} \\ 0, & \text{otherwise} \end{cases}$$

Integrated EMG (IEMG)

Integrated EMG refers to the summation of absolute values of EMG amplitude for each time segment. IEMG feature is also used for clinical applications and could be expressed as,

$$IEMG = \sum_{k=1}^N |x_k| \quad (1.8)$$

Frequency Domain Features

Investigation of EMG signal characteristics in frequency (or spectral) domain is mainly carried out to analyze both the fatigue phenomenon in

muscles and the motor unit recruitment (Kallenberg, Schulte, Disselhorst-Klug, & Hermensa, 2007). Various types of features have been proposed to handle EMG signal behavior in the frequency domain. While f_j , P_j and M represent a frequency value at a frequency bin j , the EMG power spectrum at a frequency bin j and the length of frequency bin, respectively, some of frequency domain features are given as follows.

Mean Frequency (MNF)

Mean frequency (MNF) is basically the calculation of average frequency dividing the sum of product of EMG power spectrum and frequency by total sum of the spectrum intensity. The mathematical expression is given as,

$$MNF = \frac{\sum_{j=1}^M f_j P_j}{\sum_{j=1}^M P_j} \quad (1.9)$$

Median Frequency (MDF)

Median frequency (MDF) of an EMG signal is the frequency at which the spectrum is partitioned into two equal amplitude. The MDF feature can be calculated as,

$$\sum_{j=1}^{MDF} P_j = \frac{1}{2} \sum_{j=1}^M P_j \quad (1.10)$$

Peak Frequency (PKF)

The frequency containing the maximum power is called peak frequency (PKF). The PKF can be calculated as follows,

$$PKF = \max(P_j) \quad (1.11)$$

Mean Power (MNP)

Average of power spectrum of EMG signals is used to determine the characteristics of signal. The feature could be expressed mathematically as,

$$MNP = \frac{1}{M} \sum_{j=1}^M P_j \quad (1.12)$$

Total Power (TTP)

The sum of the power spectrum of EMG signal reveals another feature, namely, the total power (TTP) and it is obtained as,

$$TTP = \sum_{j=1}^M P_j \quad (1.13)$$

Spectral Moments (SM)

Spectral moments (SM) is another important approach for feature extraction. Although higher order spectral moment could be calculated, the mathematical expressions of the first (SM_1) and the second (SM_2) order moments are given as follows, respectively.

$$SM_1 = \sum_{j=1}^M P_j f_j \quad (1.14)$$

$$SM_2 = \sum_{k=1}^M P_k f_k^2 \quad (1.15)$$

EMG signals can also be characterized in joint time-frequency domain (von Tscherner, 2000). In order to observe more accurate description of the signal in physical manner, EMG signals could be transformed to the area at which both frequency and time domain features exist. However, this transformation requires heavy computational costs and likely causes delay in controlling assistive devices. Main features of time-frequency

domain are Wavelet Transform (WT), Wavelet Packet Transform (WPT) and Short-time Fourier Transform (STFT).

The above mentioned signal features are needed to be classified to specify the intended motion and force production. To achieve this task, various types of classifiers such as artificial neural networks (ANN) (Arslan, Adli, Akan & Baslo, 2010), fuzzy logic (FL) (Chan, Yang, Lam, Zhang, & Parker, 2000), support vector machines (SVM) (Oskoei & Hu, 2008) and linear discriminant analysis (LDA) (Lorrain, Jiang, & Farina, 2011) are widely employed in literature.

FEATURE CLASSIFICATION AND PATTERN RECOGNITION

Extracted time or frequency domain features are required to be classified to determine the motion or applied force patterns (Oskoei & Hu, 2007). Characterization capability of prosthetic hands is firmly related to the classification performance of the selected classifier due to the classification accuracy reflects the fundamental neuromuscular activity of human muscles. The main consideration of pattern recognition progress of myoelectric signal is that each force or motion class is described by the corresponding muscle activation which is represented by a set of extracted features (Farina et al., 2014). The chosen classifier discriminates separate tasks using trial and test approaches, so that a relation between muscle activation, features and real-world tasks could be built. Thus, selection of appropriate classifier for pattern recognition process is a key issue which is expected to identify accurate patterns and to perform fast sufficiently. A great amount of literature exists to propose an optimal performance of classifiers and thereby selecting the most suitable one (Lorrain et al., 2011). The next section involves fundamental structures and applications of the widely used classifiers including ANN, FL, SVM and LD for the purpose of using in control of myoelectric based prosthetics.

Artificial Neural Networks (ANN)

ANN is an artificial intelligence method inspired by the biological structure of human brain and generally referred to as “neural networks” (Haykin, 1999). In human brain, the neural networks is the central of the decision making process. The receptors receive stimuli from the external environment and convert to electrical impulses in order to transmit them to neural nets. Then, neural nets perceive the information and make decision. Finally, the decision is transmitted the effectors to convert the impulses to response as outputs. Setting a linear or nonlinear relation between inputs and outputs, biological and artificial neural networks makes a specific decision.

Surface EMG feature classification using ANN is a popular subject among scientific studies related to control of human arm prosthetics. The basic structure of ANN which is used in pattern recognition process of EMG signals is shown in Figure 3.

The structure, namely the multilayer perceptron (MLP), which consists of a set of one input layer, one output layer, and a number of hidden layers is one of the most simple and commonly used type of ANN. Typical structure of an ANN, which is used for classification of EMG signal features, includes input, hidden, and output layers, so that the features could be related to different force or

position classes. Extracted EMG features are fed to ANN as a set of inputs and classified into different force or motion classes as the set of outputs. Each connection between neurons in neighboring layers such as input/hidden layers and hidden/output layers has a weighting factor (w). Moreover, hidden and output layer neurons implement a transfer function to make a mathematical relation between inputs and outputs. The transfer function $f(x)$ of input arrays x , which sets a relation between input and output data arrays, could be selected according to characteristics of the problem. For instance, a logistic sigmoid transfer function is given as,

$$f(x) = \frac{1}{1 + e^{-\beta x}} \quad (2.1)$$

where

$$x = \sum_{n=1}^k w_n a_n \quad (2.2)$$

means the total input of neuron, where w_n , β and a_n are the weight, coefficient and input of i th element, respectively. Although many transfer functions are available, the most widely used transfer functions in pattern recognition of EMG

Figure 3. Schematic representation of an artificial neural network

signals are logistic sigmoid and hyperbolic tangent sigmoid transfer functions. The number of layers and neurons are adjustable based on obtained results. Using huge numbers of training data and neurons could lead to overfitting and make a complex networks structure which has to carry out more tasks and likely produces delays. To overcome such issue, some dropout techniques could be operated and train-test proportion of data is proposed to be adjusted.

Neural networks have been utilized to obtain the closest values of output for targeting the real world results by changing the weights (training stage). Adaptation of weights is implemented according to the desired results which is called supervised learning. In the cases of supervised learning of EMG signals, desired results can be position, hand/muscle force, joint torque or motion trajectory. ANN have been operated as a classifier to predict arm and joint trajectories (Cheron, Draye & Bourgeois, 1996), to estimate hand and wrist motion trajectories in the control of a virtual hand (Sebelius et al., 2005), to classify types of limbs motion (Hudgins et al., 1993), to recognize motion patterns based on signal time scale features (Zhao et al., 2006) and to predict the kinematics of shoulder and elbow (Luh, Chang, Cheng, Lai, & Kuo, 1999).

Fuzzy Logic (FL) System

FL systems are beneficial in signal processing and classification, especially for biomedical signals which are not always repeatable, and may even be conflicting (Zadeh, 1973). One of the most useful properties of fuzzy logic systems is that discrepancies in the data can be tolerated. Moreover, it

is possible to detect the patterns in data which are not easily identified by other methods using trainable fuzzy systems. Thus, the experience of medical experts or clinicians could be integrated and benefitted. It is possible to incorporate this incomplete but precious knowledge into the fuzzy logic system, due to the system's reasoning style, which is similar to that of a human being. This is a substantial advantage over the artificial neural network (ANN). Fuzzy logic systems better reflect the human decision-making ability than the ANN (Chan et al., 2000). The fundamental of a fuzzy system is the fuzzy inferring engine. Fuzzy production rules are identified according to the available knowledge or well-classified examples (Wang, 1994).

In the fuzzy method, none of operations are random. Information involving a certain amount of suspense is expressed as reliable as possible, without the deformation of forcing it into a "crisp" mold, and it is then handled in a suitable manner. Figure 4 shows the schematic representation of a fuzzy logic system with a fuzzifier and a defuzzifier phases. Fuzzy Logic Systems architecture has three main (Figure 4). These are

1. Fuzzification Module (transforms the system inputs into fuzzy sets),
2. Fuzzy Inference Engine (simulates the human decision making process by making fuzzy inference on the inputs),
3. Defuzzification Module (transforms the fuzzy sets into output parameters).

The inference engine maps each rule's fuzzy input sets into each rule's fuzzy output set. Rules have a critical influence on the performance of a

Figure 4. Schematic representation of a fuzzy logic system

FL system. The rules operate only when the inputs are applied to them.

In order to predict the rules for a fuzzy logic system, dataset is trained. To begin, a certain number of input-output training pairs are selected. The next step is to convert the training dataset into a set of fuzzy rules (IF-THEN, IF-THEN-ELSE, etc.).

The fuzzy rules are mapping from the inputs to the outputs and this mapping can be denoted quantitatively. This kind of FL system is very common and widely used in many engineering applications, such as in fuzzy logic controllers and signal processors. It is also known as fuzzy system, fuzzy controller, fuzzy model or fuzzy expert system.

In recent years, FL systems have been used for decision making process in biomechanical science (Reaz, Hussain, & Mohd-Yasin, 2006). FLS system has been performed to control the elbow and shoulder joint angles of the exoskeletons to design a controller of multifunction prosthetics (Kiguchi, Tanaka, Watanabe, & Fukuda, 2003).

Support Vector Machines

Support vector machines (SVM) is a modern and sophisticated machine learning method (Cortes & Vapnik, 1995). Since EMG-based classification process for prosthetic control problems requires high accuracy and short duration of time to obtain outputs, SVM has become a prevalent and widely used classifier (Lorrain et al., 2011). Although the main notion of the classification progress is to assign the inputs to predefined groups or categories, SVM basically separates the classes operating an optimal hyperplane. In order to discriminate the data among a vast number of classes, a combination of multiple SVM is used. SVM classification process, briefly, is described as follows (Leon, Gutierrez, Leija & Munoz, 2011),

Let x_i and y_i are inputs and outputs, respectively, for $x_i \in R^l$ and $y_i \in \{-1, 1\}^l$. The hyperplane, which divides them into two previously determined groups, is defined as,

$$w^T \phi(x) + b = 0 \quad (2.3)$$

where w and b are weight and bias parameters of hyperplane. Additionally, ϕ is a mapping function which transforms x_i vector into higher dimensional space.

For a classification case, a various number of hyperplane could separate data into two classes. However, there must be only hyperplane, which satisfies maximum margin between the classes, is defined as,

$$\min \left[\frac{1}{2} \|w\|^2 + C \sum_{i=1}^m \xi_i \right] \quad (2.4)$$

subject to $y_i(w\phi(x_i) + b) \geq 1 - \xi_i$ and $\xi_i \geq 0$ where ξ_i is the slack variables that related to error between training data. In order to obtain optimal hyperplane with limited error equation, equation (2.4) is solved, While α_i and $k(x_i, x_j)$ are Lagrange multipliers and Kernel function, respectively, the equation is reduced as follows,

$$\max \left[\sum_{i=1}^{\infty} \alpha_i - \frac{1}{2} \sum_{i,j=1}^m \alpha_i \alpha_j y_i y_j k(x_i, x_j) \right] \quad (2.5)$$

The equation of optimal hyperplane is expressed as,

$$w = \sum_{i=1}^m y_i \alpha_i \phi(x_i, x_j)$$

which satisfies

$$\sum_{i=1}^m \alpha_i y_i = 0 \text{ and } 0 \leq \alpha_i \leq C \quad (2.6)$$

The inputs x_i which satisfy $\alpha_i \neq 0$ are called support vectors. The maximization process to build decision function of the classifier is related to choose suitable kernel function which is generally selected based on inputs type and structure.

The most common used kernel functions are linear, polynomial, sigmoid and radial basis functions. The major components of SVM is shown in Figure 5.

Lucas et al. (2008) implemented the SVM method as a supervised classification of multi-channel surface electromyographic signals with the aim of controlling myoelectric prostheses. They concluded that the SVM classification rule can be effectively implemented with fast algorithms (after training) for real-time applications.

Linear Discriminant Analysis (LDA)

Linear discriminant analysis (LDA) has become a prominent classifier with the intent of grouping very complex EMG data arrays. This section summarizes, briefly, that how LDA method works. The method is based on deriving the combination of parameters that optimally discriminates the priori defined groups (Cao & Sanders, 1996). It is assumed that the vector of features is given as $X = [x_1, x_1, \dots, x_m]$. The mean values of X for the i th class are expressed as $\mu_i = [\mu_{i1}, \mu_{i2}, \dots, \mu_{im}]$. The main procedure of LDA method is to maximize

the following function which is known as linear discrimination or gate function (Kim, Choi, Moon, & Mun, 2011),

$$f_i(x) = x^T S^{-1} \mu_i - \frac{1}{2} \mu_i^T S^{-1} \mu_i + \log(\pi_i) \quad (2.7)$$

where S is the pooled covariance matrix of input data and π_i is a prior probability of inputs coming from class i . Using the combinations of the equation, misclassification could be minimized by obtaining higher likelihood index for each defined class.

LDA method has been applied to identify EMG signals to discriminate the patterns of EMG linear envelope of healthy subjects and patients with anterior cruciate ligament injury (Alkan & Gunay, 2012) and to classify the features to enhance the controllability of a powered prosthetics (Hargrove, Scheme, Englehart, & Hudgins, 2010).

It is necessary to make an extensive evaluation of the performance of these listed classifiers in pattern recognition process besides shortcomings and merits of them. Arslan et al. (2010) employed ANN to predict externally applied forces to human hands using EMG signal features. The study, which was aimed to estimate the forces accurately, showed that the classifier predicted the targeted force values in a range of 0.34 and 0.05, and of 0.24 and 0.09 root mean square difference (RMSD) for isometric and anisometric contraction experiments, respectively. In this study it was clearly stated that ANN method could built a successful non-linear relation between force and EMG signal features. However, the authors highlighted that it is not possible to propose a standard ANN design for training the EMG signal efficiently. Even though ANN is a powerful classifier, the absence of a conceptualized and standardized training method represents an important disadvantage.

Chan et al. (2000) performed a fuzzy logic based classification procedure to control prosthetics. They also provided a comparison between ANN and fuzzy systems in pattern recognition process. In the study, it was shown that 8% and

Figure 5. The basic representation of support vector machine. Optimal hyperplane is represented with solid line which divides optimal margin between two classes. Square and triangle on dashed lines are support vectors.

11.3% of error rates were obtained by Fuzzy and ANN classifiers in pattern recognition, respectively. Some advantages of fuzzy systems were listed as *i)* slightly higher recognition rate than obtained by ANN, *ii)* insensitivity to overtraining, and *iii)* consistent outputs demonstrating higher reliability. The main drawback of the method was noted that requiring more human intervention at initialization stage in order to get the minimum inter-class cross-over. Hence it was stated that the procedure is not automatic to the same extent as ANN.

LDA is becoming a prominent tool for pattern recognition in EMG studies. Chu et al. (2007) conducted a study which includes an EMG feature discrimination process. After a real-time pattern-recognition progress, it was shown that the proposed method achieves the recognition accuracy rate of 97.4%. Phinyomark et al. (2013) also reported that LDA shows a better performance in the classification of fluctuating EMG signals compared to several classifiers such as quadratic discriminant analysis (QDA), random forests (RFs) and k-nearest neighbor (KNN).

The performance of SVM as a machine learning method is needed to be assessed. Subasi (2012) compared the performance of a group of classifiers and reported that classical SVM method provided 96.75% accuracy, while the kNN and the radial basis function (RBF) classifiers achieved the process with 95.17% and 94.08% accuracy, respectively. In the study, it was also noted that SVM performance could be enhanced with some modifications.

FUTURE RESEARCH DIRECTIONS

Though rapid improvements of assistive technologies and specifically artificial human hand prosthetics have been observed, challenging problems are still remaining to be solved in terms of EMG signal pre- and post-processing operations with the intention of providing dexterous control of prosthetics.

Feature Selection

Features extracted from EMG signals for both in time and frequency domains are used at present. However, new features may be proposed for better representation of EMG signals. Furthermore, effect of sliding windows for calculation of features should be investigated in detail. Used features presently are calculated by means of differentiation or summation of neighboring EMG signal amplitudes. New approaches such as measuring energy consumption for each EMG signal maybe employed for time domain in future studies, as well.

Classification Methods

The classifier performance is investigated by researchers extensively. Selection of training and test data for discrimination process has a great influence on classification accuracy and operation duration. Selection of the optimum cross-validated EMG signal arrays should be a purpose of next studies. Additionally, using the combinations of time and frequency domain features for training and test may provide higher accuracy of classification. Furthermore, semi-supervised learning, which is one of the fundamental aspects of classification methodology for cases that it is hard to obtain sufficient training data, should be studied in more detail.

CONCLUSION

The chapter provides a general overview on the EMG signal features and their classification methodologies which are critical issues for controlling of human arm prosthetics. EMG-driven human arm prosthetics are highly sensitive to the scientific and technological advances. Through the last decades, many of EMG signal features calculation and discrimination methods have been proposed and applied to prostheses. Precise and intuitive control of prosthetics depends mainly upon the type of extracted feature and classifica-

tion techniques. Making a significant difference or advancing the dexterity in the control of prosthetic devices depend on achieving the optimum signal feature and classifier architecture. Needless to say that in addition to the control structure, mechanical structure of the prosthetics also plays a major role in the completion of complex motor tasks which deserves to be extensively dealt with in a separate report.

KEY TERMS AND DEFINITIONS

Assistive Technology: A branch of technology is used to regain the lost functions of human body parts.

Feature Classification: A pattern recognition technique that is used to categorize a huge number of data into different classes.

Feature Extraction: A method to obtain meaningful and clear data of a signal.

Human Arm Prostheses: Assistive devices which enable to perform lost functions of human arm due to upper or lower arm amputations.

Pattern Recognition: A machine learning process which identifies the pattern of physical systems using data belong to investigated systems.

Rehabilitation: A series of therapy to make injured or amputated people regained lost skills or functions.

Surface Electromyography: A type of electromyography signal recording method carrying out by means of adhering electrodes to skin surface.

The Principle and Process of Digital Fabrication of Biomedical Objects

INTRODUCTION

Mounting pressure of market globalization and intensifying competition has ferociously been driving the manufacturing industry to survive on incessant reductions in cost and lead-time. However, conventional manufacturing methods can no longer satisfy increasingly diverse customer demands, tight cost control, and complex new products.

Against this background, much research efforts have been devoted to developing various technologies to help the manufacturing industry, and layered manufacturing (LM, or now often called 3D printing) and virtual reality (VR) simulation have been among the most significant technologies developed over the past couple of decades.

Despite recent proliferation of LM (3D printing) for free-form fabrication, most of the current systems can only fabricate objects of a single material (Wohlers Report, 2013). There are imminent demands for multi-material layered manufacturing (MMLM) processes to fabricate advanced products and biomedical objects comprising of multiple materials. A few experimental MMLM machines have been developed based on the conventional single material LM systems for relatively simple objects (Bellini, 2002; Wang & Shaw, 2006; Wachsmuth, 2008; Li et al, 2009; Åklint et al, 2013). However, their fabrication

speed is unsatisfactory for most complex, large products or medical objects for emergency cases.

More recently, many researchers have worked on virtual prototyping and virtual manufacturing (VPM) (Bracht and Masurat, 2006; Wang and Li, 2006), which is regarded as one of the most important technological advancements for product design and development. VPM has been successfully used in ship-building and car industries (Kim et al, 2002; Wöhlke and Schiller, 2005). It uses simulation techniques to analyze and improve a product design and validate the fabrication processes and production schedules.

Through simulations in a VR environment, key factors such as the product shape, manufacturability, and durability that may affect the profitability of manufactured products are optimized. VPM enhances profitability by reducing production cost and material usage, etc. Moreover, it reduces time and tooling cost by eliminating the need for multiple physical prototypes. This allows the users to review and validate a product design to “get it right the first time” for delivery of quality products to market on time and within budget.

This chapter describes the principle of virtual prototyping and virtual manufacturing, with a focus on the processes of modeling and subsequent digital fabrication of multi-material biomedical objects. Case studies of modeling and digital fabrication of biomedical objects using a multi-

material virtual prototyping and manufacturing (MMVPM) system will be presented to demonstrate its principle and possible applications in biomedical engineering.

BACKGROUND

There has been a huge surge in demand for biomedical objects in recent years for various medical and dental purposes (Khan & Dickens, 2014; Lee et al., 2001; Maji et al., 2014; Pinnock et al., 2016; Ripley et al., 2016; Sanghera et al., 2001; Winder et al., 1999).

Biomedical objects have been traditionally used as prostheses to repair damaged bone structures or to replace missing body parts (D'Urso et al., 2000; Eufinger et al., 1995; Sannomiya et al., 2008). They are now commonly used by medical students, surgeons, and dentists to help study the intricate anatomical details of human organs and bone structures, as well as to facilitate planning of implantations and surgical procedures (Singare et al., 2009). For example, artificial hip joints, and bone and jaw structures are often used in hospitals to assist complex medical operations. In addition, they are used as specimens for experiments in pharmaceutical manufacturing enterprises.

Depending on the required properties and applications, biomedical objects can be made of either homogeneous (single) material, or heterogeneous (discrete multiple) materials, or functionally graded materials (FGM) (Pompe et al., 2003; Sun et al., 2005). Watari et al. (2004) described the fabrication of an FGM dental implant by powder metallurgy. Experimental results showed that the implant could achieve better mechanical properties and biocompatibility, and that it could control the tissue response through the gradient function of FGM.

But over the years, biomedical objects have been getting more complex, both geometrically and structurally, with more intricate internal details and delicate material variations. As such, most biomedical objects are not economical, and

very often not possible, to make by the traditional manufacturing processes.

To fabricate biomedical objects of multiple materials, some researchers have explored the MMLM technology, which is a layer-by-layer additive process that fabricates a heterogeneous object of a number of different materials, which can be discrete with distinctive boundary interfaces, or functionally graded with composition gradients changing gradually from one to another. This process requires a computer-aided design (CAD) model with sufficient material information (Gu and Li, 2002; Gupta et al., 2015; Jafari et al. 2000; Sun et al., 2005).

MMLM, however, remains experimental, and its practical application for fabricating biomedical objects is limited. Indeed, most current MMLM systems can only handle relatively small, simple objects of few materials. More importantly, they are slow and expensive to operate. To address the limitations of MMLM, research efforts have recently focused on developing multi-material virtual prototyping and manufacturing (MMVPM) technology for digital fabrication of complex biomedical objects in a convenient and cost-effective manner.

MMVPM provides a digital platform that integrates virtual reality (VR) simulation technique with MMLM processes. It is an effective tool that can digitally fabricate complex biomedical objects for use in lieu of physical ones. The user can model a complex biomedical object and digitally fabricate its prototypes. Subsequently, the resulting digital biomedical prototypes can be visualized and analyzed in a VR environment, as if the user is manipulating physical objects, for some medical and dental purposes.

The following sections describe the workflow of the MMVPM system in detail. Case studies of modeling and subsequent digital fabrication of biomedical objects using MMVPM would be presented to demonstrate the principle and process of digital fabrication of complex objects for possible applications in biomedical engineering.

THE MMVPM SYSTEM FOR DIGITAL FABRICATION OF BIOMEDICAL OBJECTS

The MMVPM system consists of a suite of software packages for design and visualization of discrete and functionally graded multi-material biomedical objects and simulation of MMLM process in a VR environment. These packages include a color modeler for coloring monochrome STL models, a slicing algorithm, a topological hierarchy-sorting algorithm for grouping random slice contours, a topological hierarchy-based toolpath planning algorithm for generation of sequential and concurrent multi-toolpaths, and a virtual prototyping and virtual manufacturing (VPM) module for digital fabrication of the multi-material biomedical objects (Choi and Cheung, 2005, 2007, 2009; Choi and Kwok, 2004).

Figure 1 summarizes the three major processes for digital fabrication of biomedical objects, namely:

1. Data acquisition for model generation of biomedical objects;
2. Model processing, contour slicing, and toolpath planning for digital fabrication;
3. Digital fabrication, visualization and analysis of biomedical objects.

Data Acquisition for Model Generation of Biomedical Objects

To acquire data for generation of a biomedical model, a target anatomical structure is firstly scanned by a medical imaging device, like CT, μ -CT, and MRI, to generate 2D image slices. The resulting 2D slice images in grayscale are then imported into a 3D construction software, such

Figure 1. The main processes of digital fabrication of biomedical objects

Figure 2. Generation of a 3D pelvis model and a 3D human skull model from 2D image slices by 3D-DOCTOR

Source: Able Software Corp, 2011

as Materialise Mimics and Able Software Corp 3D-DOCTOR, to extract characteristic data points and subsequently generate the required biomedical model, normally in STL format, which is the de-facto industry standard for layered manufacturing (Sun et al., 2005; Wang et al., 2010). Figure 2 shows two screen captures of the 3D-DOCTOR generating a 3D pelvis model and a 3D human skull model from respective 2D slice images (Able Software Corp, 2016).

Model Processing, Contour Slicing, and Toolpath Planning for Digital Fabrication

The resulting biomedical STL model is then processed in the MMVPM system to add material information, generate slice contours, and plan toolpaths for subsequent digital fabrication and visualization of the resulting biomedical object, as follows:

1. An in-house package is used to paint the biomedical STL model (which is originally monochrome of a single material), with each color representing a specific material;
2. The color STL model is sliced into a number of layers of a predefined thickness. The

resulting slice contours and material information are stored in a modified Common Layer Interface (CLI) file;

3. The slice contours are sorted with a contour sorting algorithm to establish explicit topological hierarchy;
4. Based on the hierarchy information, a multi-toolpath planning algorithm is used to plan and generate toolpaths for concurrent deposition of materials by hatching the slice contours with a predefined hatch space. The hatch vectors are stored in the modified CLI file for fabrication of biomedical object and build-time estimation.

Digital Fabrication, Visualization and Analysis of Biomedical Objects

The toolpaths together with the hatch vectors are subsequently input to a VP module to perform digital fabrication of the biomedical object. The resulting digital biomedical object can be visualized and analyzed, as if manipulating a physical one, to review and improve the design of the biomedical objects conveniently. Although the digital biomedical object can be displayed on a general computer monitor or projection screen, it is preferable to visualize and analyze it in a VR

environment to take advantage of the stereoscopic views and immersive feelings.

The following section uses a human mandible to be inserted with surgiguides to demonstrate how the MMVPM system can model and fabricate multi-material objects for biomedical applications, such as surgical training and planning, patient's education, and implantations.

Figure 3 shows a multi-material assembly of a human mandible inserted with two surgiguides. To ensure the required implant precision, virtual models of the human mandible will be useful to simulate and study possible treatment plans. The MMVPM system can be used to assist surgeons to study a treatment plan through stereoscopic visualization and analysis of a human mandible prototype with surgiguides, as shown in Figure 4.

The surgiguides facilitate positioning the implant accurately. Based on the treatment plan resulted from the simulation, surgeons can improve the design of the surgiguides to fit the patient's bone structure. Figure 5 shows the complete process of digital fabrication of the mandible prototype, while its quality can be visualized accordingly in Figure 6.

It can be seen in Figure 6 that areas of dimensional deviations scattered mainly around the teeth and the bottom of the mandible bone, while the surgiguides are relatively smooth. This is considered satisfactory as we are more concerned with the accuracy of the surgiguides.

Figure 3. A color STL model of a human mandible with two surgiguides

Nevertheless, the simulation process can be iterated with a new combination of process parameters to improve the accuracy of the surgiguides, if necessary. Therefore, based on stereoscopic visualization and deviation analysis, satisfactory designs can be enhanced and validated for subsequent fabrication of dental implants in a convenient and cost-effective way.

To achieve best surgical results possible, an implant should preferably be made of functionally graded materials with properties that would mimic the biological and mechanical characteristics of human organs or tissues (Krishna et al., 2008; Lin et al., 2009; Watari et al., 2004). The MMVPM system can design and digitally fabricate FGM objects to assist such purposes.

For example, it would be desirable to have dental implants made of functionally graded materials, such as titanium (Ti) and hydroxyapatite (HAP), to satisfy both mechanical and bio-compatible

Figure 4. Stereoscopic visualization of a human mandible prototype with surgiguides

properties. Figure 7 shows the resulting FGM dental implant, with material variation represented by blending of red (100% HAP) and green (100% Ti) colors along the Z-axis. Figure 8 shows the resulting FGM teeth.

CASE STUDIES

To further demonstrate possible use of the MMVPM system for modeling and digital fabrication of biomedical objects to facilitate complex surgical procedures, a human ear model and a human thorax model are illustrated in this section.

Case Study One: A Human Ear Model

Hearing loss is one of the common diseases of human ears. It may be caused by genetic problems, harmful noises from working environments, and ageing, etc. (McCullagh, 2011). Some possible clinical approaches include cochlear implant and tympanum (eardrum) repair (Huber & Kipman, 2011). For this purpose, a digitally fabricated human ear model would be particularly cost-effective and convenient to help surgeons diagnose the disease and plan the possible surgical operations. Therefore, to make one, a monochrome human ear STL model is firstly painted with an in-house package to highlight various parts of the model, as shown in Figure 9.

Figure 5. Digital fabrication of the human mandible prototype with surgiguides

Figure 6. Areas of the human mandible prototype with dimensional deviations beyond design limits

B

Figure 7. A functionally graded dental implant generated by the MMVPM system

Figure 8. FGM teeth

Figure 9. A color STL model of an anatomical human ear

Figure 10. A slice of the ear model consisting of four materials

Based on the geometric and material information provided by the color STL model, the ear model is sliced into a number of layers with a predefined layer thickness. Figure 10 shows the slice contours of a particular layer to be made of four materials colored in orange, pink, blue, and grey. The contours of each layer are then sorted to obtain explicit topological hierarchy information for planning and generation of toolpaths for concurrent deposition of materials. Subsequently, a human ear prototype with discrete multi-materials can be digitally fabricated using the VPM module. Figure 11 shows some stages of the digital fabrication process and the resulting discrete multi-material prototype of the human ear model. Indeed, a digital multi-material prototype of a human ear would be particularly useful for study and planning of delicate surgeries, in that they can differentiate clearly one part from another, or tissues from blood vessels of the ear.

Case Study Two: A Human Thorax With an Intervertebral Disc Spacer

Figure 12 shows a color STL model of a human thorax, which consists mainly of three parts: the ribs, the sternum, and the spine. Based on the

geometric and material information provided by the color STL model, the MMVPM system can slice the thorax model into a number of layers, one of which is shown in Figure 13. The layer contours are then sorted to obtain explicit topological hierarchy information for planning and generation of toolpaths for concurrent deposition of materials. Subsequently, a thorax prototype with discrete multi-materials can be digitally fabricated using the VP module. Figure 14 shows parts of the digital fabrication process.

The resulting digital thorax model would be particularly useful for studying related symptoms like back pain, which is among the frequently reported musculoskeletal problems. The most common factor causing low back pain is the degeneration of intervertebral discs. Taksali et al. (2004) reported that back pain can result from irritation of the surrounding sinuvertebral nerves when the nucleus extrudes into annular tears.

To alleviate this problem, it may be necessary to replace the degenerated disc with an artificial intervertebral disc spacer to remove the primary pain generator while preserving functional motion. As shown in Figure 15, an artificial intervertebral disc spacer has to be inserted between two adjacent vertebrae. For this purpose, it would be

Figure 11. Digital fabrication of a prototype of the human ear model

medically preferable to make such a disc spacer with materials having functional and biocompatible properties similar to a normal disc.

The artificial intervertebral disc is to be composed of three components, namely the nucleus pulposus, the annulus fibrosus, and the vertebral endplates, as shown in Figure 16. In comparison with the material property of the annulus fibrosus, the nucleus pulposus is softer while the endplates are harder.

Parsons et al. (1992) invented a molding method to fabricate a functional and biocompatible intervertebral disc spacer. The disc spacer consisted of:

1. A central core of a biocompatible elastomer with a hardness in the range of 20-70 shore-A, shaped and sized to approximate the nucleus pulposus of a natural intervertebral disc, and
2. An outer ring of elastomeric material with a hardness in range of 40–80 shore-A, surrounding the central core to approximate the size and shape of a natural annulus fibrosus.

The endplates comprised a biocompatible elastomer with a hardness in range of 90-100 shore-A, and affixed, one to each end, to the outer ring / central core. The relative size of the central core and the thickness of the outer ring in the radial direction, and the selection of material hardness, could be varied in order to better match the mechanical properties of the composite prosthesis with that of the normal disc. The disc spacer could thus achieve the desired properties by varying the hardness of the elastomeric material along the circumferential and the Z-axis directions of the spacer, respectively, by changing the composition of the elastomeric material.

It is therefore desirable to design and fabricate an FGM intervertebral disc spacer with a gradual change of compositions of the elastomeric material to achieve the desired hardness properties in order to mimic the normal disc in an intervertebral disc prosthesis.

The MMVPM system can also be a practical tool to model an FGM intervertebral disc spacer with a functional gradation in hardness property,

Figure 12. A color STL model of a human thorax

Figure 13. A slice of the thorax model consisting three materials

and then build a digital prototype to facilitate visualization and subsequent fabrication.

To represent the material variations of the intervertebral disc spacer, it is firstly sliced into a set of homogeneous layer contour-based model, and explicit topological hierarchy information is then built for each layer. Secondly, feature layers are selected for assigning primary materials and material control functions for calculation of property values of material composition. Thirdly, each layer is discretized into sub-regions of constant material composition.

Figure 14. Digital fabrication of a prototype of the human thorax model

Figure 17 shows the resulting FGM intervertebral disc spacer with 3D variations of material composition. Along the Z-axis, it has a material variation represented by blending of blue (100

Figure 15. An artificial intervertebral disc spacer inserted between two adjacent vertebrae

Figure 16. The structure of an intervertebral disc

shore-A elastomer) and red (60 shore-A elastomer) colors; at the same time, there is material variation of each layer in the X-Y plane.

Now, the resulting contour-based FGM intervertebral disc spacer model has both geometric and material information to be processed for visualization of internal material variation of each layer,

multi-toolpath planning, and subsequent digital fabrication. Figure 18 shows various stages of the digital fabrication process of an FGM intervertebral disc spacer prototype. The MMVPM system allows adjustment of the resolution of material composition to suit practical visualization and fabrication requirements, simply by changing

Figure 17. An FGM intervertebral disc spacer with material variations along the Z-axis and in the X-Y plane

Figure 18. Digital fabrication of an FGM intervertebral disc spacer prototype

the discretization of layer contours, which is the number of layers and the number of sub-regions. Therefore, it is a practical tool for modeling and digital fabrication of biomedical objects with FGM and discrete materials.

FUTURE RESEARCH DIRECTIONS

Although the MMVPM system presented above provides a convenient digital platform that integrates VR simulation technique with MMLM processes for virtual prototyping and virtual manufacturing of complex multi-material objects

for advanced product development and biomedical applications, it is limited by its local connectivity and there is a lack of cloud computing capability for remote processing.

Therefore, a worthwhile future development of the MMVPM system is to enhance the algorithms of its main modules for integration with cloud-based computing technology to facilitate remote image processing and visualization of digital fabrication processes. As such, users who are geographically separated can participate in the discussion and sharing of digital fabrication of complex multi-material objects simultaneously for different applications.

CONCLUSION

This chapter described the workflow of a multi-material virtual prototyping and manufacturing (MMVPM) system, which is a digital platform that integrates VR simulation technique with MMLM processes. Case studies of modeling and digital fabrication of biomedical objects using the MMVPM system were presented to demonstrate its principle and possible applications in biomedical engineering. The case studies showed that the MMVPM system is a convenient and cost-effective tool that can digitally fabricate complex biomedical objects for use in lieu of physical ones. The user can model a complex biomedical object and perform fabrication simulation. Subsequently, the resulting digital biomedical object can be visualized and analyzed in a VR environment conveniently for some medical and dental purposes.

ACKNOWLEDGMENT

The authors would like to acknowledge the Committee on Research and Conference Grants (CRCG) of the University of Hong Kong for partial financial support for this project.

KEY TERMS AND DEFINITIONS

Biomedical Object: An object made of bio-compatible materials for prosthetic or bioengineering applications.

Digital Fabrication: Graphical simulation of a fabrication process to make an object in digital form.

Multi-Material Layered Manufacturing: An additive manufacturing process for fabrication of a multi-material object layer by layer.

Multi-Material Object: An object made of a number of heterogeneous (discrete) materials or functionally graded materials.

Multi-Material Virtual Prototyping and Virtual Manufacturing: Graphical simulation of a multi-material layered manufacturing process to make a multi-material object in digital form.

Reverse Engineering in Rehabilitation

B**Emilia Mikołajewska***Nicolaus Copernicus University, Poland***Marek Macko***Kazimierz Wielki University, Poland***Zbigniew Szczepański***Kazimierz Wielki University, Poland***Dariusz Mikołajewski***Kazimierz Wielki University, Poland*

INTRODUCTION

Reverse engineering is relatively novel technology, which may revolutionize clinical practice in rehabilitation. This technology may constitute next step toward patient-tailored therapy, providing customized medical products increasing effectiveness and accessibility of rehabilitation procedures and decreasing cost of manufacturing and time of delivery. Such opportunities need separate research, assessment of associated threats, and dedicated solutions.

In this chapter authors investigate the extent to which the available opportunities in the area of application of reverse engineering in rehabilitation are being exploited, including own concepts, studies and observations.

BACKGROUND

The additive manufacturing (AM), called also 3D printing or stereolithography is relatively novel technology developing since 1980s. It constitutes iterative technology based on construction the real objects layer by layer, translating this way digital file (digitized object) into a solid object. Features of such object depend on technology and material used to print, but number of both of them rapidly

increases, providing important alternative for traditional manufacturing techniques. Moreover some objects have unique features (e.g. shapes) not comparable with products of traditional manufacturing.

Recent editorial article by Maruthappu & Keogh paid particular attention to potential of 3D printing applications to transform healthcare technologies and organization. Authors divided possible healthcare applications of additive manufacturing into three main groups:

- Internet as decentralised store of blueprints (drugs, equipment, devices, and even body parts) for Early patients-tailored interventions, much quicker and cheaper than traditional delivery solutions,
- Patient-tailored therapy based on medical imaging combined with 3D printing,
- Engineering of 3D printed tissues (Maruthappu & Keogh, 2014; Murphy & Atala, 2014; Seol et al., 2014).

Further implementation of reverse engineering needs additional interdisciplinary research (including randomized controlled trials on patients where available), dedicated methodology, careful assessment of opportunities and threats as far as dedicated solutions.

Reverse Engineering as A Complex Process

Reverse engineering is regarded as quick and cost-effective method of creating functional or nonfunctional copies of existing objects. Process of reverse engineering for rehabilitation purposes is unified to several subsequent stages covered by semi-automated process:

- Digital acquisition of the 3D geometric data: directly from the patient or based on his/her medical records (e.g. using computed tomography – CT or magnetic resonance imaging – MRI),
- Modification/adaptation procedures,
- Creation of 3D model or final product on 3D printer and control of its feasibility: material features, shape, dimensions, patient comfort, etc.

Reverse Engineering for Rehabilitation Support Purposes

Rehabilitation aims at restoration of patient's functions to the maximum possible degree. Scientists and clinicians are aware that in such person the full capacity available in healthy people can not be achievable despite efforts of patient, therapists and caregivers. Increasing number of severely ill, disabled and elderly people makes this task even more difficult. Thus there is still need for novel solutions increasing effectivity of the current rehabilitation procedures.

Rehabilitation should be common, early, comprehensive, and continuous. Reverse engineering products are beneficial for a wide variety of applications in the area of rehabilitation providing:

- Short track between measurements in particular patient and final ready-to-use patient-tailored product (assistive technology device, drug, artificial organ),

- The same quality, geometric accuracy and shape reconfiguration possibilities as original product (e.g. in the case of replacement),
- Features modification possibility (according to the current patient's need) by therapists/manufacture,
- Low price thanks to cheaper commercial technologies of 3D printing, lack of transport and storage costs,
- Cost-effective production of customized products.

Reverse engineering can provide cells based bones or soft tissues for modelling, testing and therapy purposes thanks to the use of bio-ink (composition of cells and hydrogel materials). Moreover assistive technology products can be cheaper and patient-tailored. Use of such solutions can provide higher therapy efficacy, life quality in patients with severe disorders, usually associated with long-term disability. The huge breakthrough in neurology, neurosurgery and neurorehabilitation can cause novel nerve repair technique: microstructured scaffolds to promote nerves regeneration (Chang et al., 2008; Zhu et al., 2008).

SOLUTIONS AND RECOMMENDATIONS

There is need for further development of interdisciplinary collaboration to identify possible threats and limitations emerging from novel applications of the reverse engineering in everyday clinical practice. Current limitations in the area of reverse engineering cover following topics:

- Ethical issues concerning use of living tissue to print artificial organs, and possible tissue modifications,

- Legal issues including copyright laws to printed copies, patents and original-based hybrid solutions,
- Lack of commonly approved standards of quality,
- Lack of quality and development of internet-based blueprints supervision,
- Lack of control on printed medical devices, especially in poor and developing countries,
- More complex emerging issues concerning eugenics and military applications (Maruthappu & Keogh, 2014).

Novel imaging techniques, printing techniques and software encouraging reverse engineering will constitute challenge for medical education system, due to required specialistic knowledge and experience. Graduate and postgraduate education of medical staff should incorporate novel standards of interdisciplinary co-operation, within patient-tailored therapy. Local scientific and clinical authorities should incorporate modified evidence-based clinical guidelines, paying particular attention to possible secondary changes in patients.

Important limitation constitutes variability of materials and associated techniques of 3D printing. Current materials for 3D printers are limited to plastic, metal, ceramics and living cells. Material engineering faces to biomaterials with features desired for surgical handling, encouraging tissue reintegration, anti-allergic, water-resistant, non-fragile or even biodegradable materials. Natural materials (wood, leather) may be hard to replace. Also combining various materials (e.g. metal and plastic) within one printable product still constitutes a challenge. Increasing use of E-health technologies can change face of the healthcare in the future.

Traditional manufacturing technologies (e.g. welded) in selected cases can provide better solutions than 3D printed. Thus key element of further development in the area of reverse engineering is integration of 3D printed objects with existing approaches.

Despite aforementioned problems many successful products have resulted from this approach:

B

- Surgical management and strategy of rehabilitation of acetabular fracture showed accurate and safer surgical management, shorter postoperative recovery time and significantly decreases costs (Deng et al., 2014, Klein et al., 2013),
- Full-arch prostheses of edentulous mandibles (De Santis et al., 2013),
- Customised foot orthoses (Telfer et al., 2013),
- Customized Gensingen braces (Bibb & Brown, 2000; Weiss, 2010),
- Dental technologies (Shahmiri et al., 2014; Yuan et al., 2013; Giordano et al., 2012; Leijnse & Spoor, 2012),
- Urological practice (Youssef et al, 2015),
- Various other easy to use and effective assistive technology solutions (Watanabe et al., 2015).

Rapid development of hardware and software allows for expectations concerning novel technologies in the area of 2D to 3D images conversion as far as rapid reconstruction of the anatomical parts based on CT and MRI. There is need for effective and accurate, but relatively simple, quick and cheap solutions dedicated for medical applications. Errorless (even semi-automatic) reproducing of natural affected anatomy can significantly decrease time of recovery in patients after severe injuries.

Development of stem cell based 3D printing can make another breakthrough not only in everyday clinical practice (e.g. reduce mortality in burns or vascular diseases) but also in medical ethics and law regulations concerning transplantation procedures. Lack of physical person (donor) and possibility to print artificial organ as copy of original organ can positively affect public awareness and public opinion playing an important role in increasing organ donation. Clinicians should be aware that it may take a lot

of years to print some complex organs as heart and avoid complications.

Another challenge remains integration with other future therapies like nanomedicine, nanorobotics and bioMEMS. There is need for closest co-operation of whole interdisciplinary research teams.

FUTURE RESEARCH DIRECTIONS

Important directions for further research are multifunctional designs that combine geometric and material complexity, such as self-folding 3D printed structures, actuated in a heating environment (Deng & Chen, 2015; Gao et al., 2013; Ishida et al., 2014). Further research on bio-inspired design can help understand the mechanisms underlying many associated cognitive processes (Fu et al. 2014), as well as results of the Human Brain Project (Rose, 2014; Markram, 2012).

Current evidences concerning use of reverse engineering in rehabilitation are regarded as insufficient. There is strong need for further research exploring novel area of applications, e.g. semi-natural bones and tissues, associated with bone kinematics and dynamics simulation (Fang et al., 2015; Wei & Dong, 2011; He et al., 2014). Our own research concern three main topics:

- Use of various technologies and materials to print 3D patient-tailored assistive technology (Lei et al., 2014),
- Research on mechanical properties of printed objects,
- Easy acquiring and modification of existing patients' electronic health records, including medical imaging, as an useful source of templates for reverse engineering.

Further challenge constitutes development of family of novel reverse engineering tools (including user-friendly software) for clinical staff - allowing for easy adjustment of the digital models/patterns to the needs of the particular pa-

tient (Macko et al., 2016). Industrial 3D printers and associated technologies may reach extremely high resolution, but everyday use of 3D biomaterial printers and 3D desktop printers is limited. Moreover cost-effect factors associated with aforementioned solutions are hard to compare. Use of bio-ink has still many limitations: limited number of bio-plotting materials, limited resolution and strength, complex technology, timing of gelation time, degradation kinetics, and influence of byproducts (even biodegradable). Simultaneous printing using multiple biofactors and materials is hard to achieve. But the room temperature of processing and homogenous distribution of cells makes bio-printing the most useful and promising technology do far.

Even attempts of low-cost fabrication the soft prostheses with the help of a desktop 3D printer were recently reported (He et al., 2014), but every novel medical technology needs careful studies to prove its safety for patients and therapists, and avoid possible complications and secondary changes (even as long-term effects). On-demand production of drugs must provide patient safety (e.g. dose precision, drug features and effects) and quality similar to the drugs manufactured using traditional technologies (Weismann et al. 2015).

Quick development of 3D printing and reverse engineering creates novel solutions and challenges every day: 95.8% of plastic surgeons want CT- or MRI-derived models for their patients (especially as low-cost solutions for facial transplantation and reconstruction purposes). There is common belief that use of 3D printed models and reverse engineering should be incorporated into graduate and postgraduate medical education. This way preoperative planning, developing intraoperative guidance tools, producing patient-specific prosthetics, and teaching patients and surgeons in everyday clinical practice may be easier, and post-operative comfort and esthetics can be optimized (Chia & Wu, 2015; AlAli et al., 2015; Chae et al., 2015; Jones et al., 2015, Chi & Kim, 2015; Wu & Hsu, 2015; Gerstle et al., 2014).

CONCLUSION

Proposed approach—reverse engineering -enables us to design and manufacture relatively complex objects from its original structures or digitized images. It poses intriguing research questions to its further applications in rehabilitation and possible novel research. It can make key contribution to safe human health and improve the quality of life of patients with functional deficits. Such powerful solution needs for careful further research on larger samples, follow-up studies, and more advanced analytical measurements and technical assistance.

KEY TERMS AND DEFINITIONS

3D Printing: Technical process of building physical objects from a three-dimensional (3D) digital model by adding many subsequent thin layers of special building material (plastic, metal, etc.).

Assistive Technology: Technology used in an assistive technology device or assistive technology service.

Assistive Technology Device: Equipment used to increase, maintain, or improve functional abilities of disabled people.

Biomedical Engineering: Application of principles and practices of engineering science to biomedical research and everyday clinical practice in health care.

Health-Related Quality of Life (HRQoL): Multi-dimensional concept covering the overall condition of a human life in areas associated with impact of the health status on quality of life: physical, mental, emotional, and social functioning.

Physical Therapy: Use of physical therapy methods, techniques and tools to promote, maintain, or restore the physical and physiological well-being of an individual with movement dysfunction.

Quality of Life (QoL): Multi-dimensional concept covering the overall condition of a hu-

man life in various areas: physical, emotional, social, political, moral, etc., their modification and enhancement.

Recovery of Function: A complete (where available) or partial return to the normal (or maximum degree) physiologic activity of an organism following disease or trauma.

Rehabilitation: Process of restoration of human functions to the full (or maximum possible) degree in patients suffering from disease or injury.

Rehabilitation Engineering: A part of biomedical engineering: application of engineering science to design, develop, adapt, test, evaluate, apply, and distribute technological solutions to problems associated with disabilities in areas of mobility, communications, hearing, vision, and cognition.

Reverse Engineering: Quick and cost-effective method of creating copies or modified versions of existing objects, unified to three subsequent stages: digital acquisition of the 3D geometric data, modification/adaptation procedures, and creation of 3D model or final product on 3D printer.

Universal Design: Concept for designing and delivering products and services usable by people with the widest possible range of functional capabilities (including people with various deficits).

Acceptance of E-Reverse Auction From the Buyer Perspective

Cigdem Altin Gumussoy

Istanbul Technical University, Turkey

Bilal Gumussoy

Shell and Turcas Petrol Inc., Turkey

INTRODUCTION

With the advances in internet technologies, an e-reverse auction becomes a popular way of procurement of products and services. E-reverse auction is “an online, real-time dynamic auction between a buyer organization and a group of pre-qualified suppliers who compete against each other to win the business to supply goods or services that have clearly defined specifications for design, quantity, quality, delivery, and related terms and conditions” (Beall et al., 2003, p.7). E-reverse auction is first introduced in 1995 by FreeMarkets Online and since then the number of users has dramatically increased.

E-reverse auction initiates with the preparation of a request for quotation (RFQ) by the buyer, which includes the information about the specifications of the products or services to be auctioned. The format of the auction such as historical price, bid decrement and auction starting time is discussed and agreed with the suppliers and the buyer before the auction (Mithas and Jones, 2007). Suppliers all over the world without any geographical limitation can participate to the auction if qualified by the buyer to join. This increases the competition and the chance to find most capable supplier with unique capabilities (Hartley et al., 2004; Lucking-Reiley, 2000). At the starting time, all the potential suppliers log in to the system, start to compete and bid against each other. However, the participants do not see their

identity and generally see the lowest bid value and their rank with respect to the other participants or their rank only. Each participant may submit multiple bids during the auction. This competitive environment can lead to great price reductions for the items auctioned. In addition, cycle-time savings for buyers and suppliers, growing markets, accessing to a larger pool of suppliers can be the other advantages of e-reverse auction use (Schoenherr and Mabert, 2007; Mithas et al., 2008).

On the other hand, using e-reverse auction includes risks such as damaging supplier relationships, switching to a supplier who cannot satisfy the quality requirements, increasing the total cost of procurement, the need to invest in technology, distrust to a new supplier about the responsiveness and flexibility to the changes in demand (Schoenherr and Mabert, 2011; Mithas et al., 2008; Hartley et al., 2006). Therefore, there may be resistance from internal users and suppliers for possible risks or underestimation of the benefits of e-reverse auction use (Schoenherr and Mabert, 2007).

In the current study, a research model including risks and benefits of using e-reverse auction is proposed in order to reveal the important factors in the decision to use e-reverse auction. Furthermore, the effect of organizational characteristics such as firm size, information technology (IT) capability and managerial support on the usage decision are discussed in the research model. The next section discusses the literature on e-reverse auction use.

This section is followed with a research model on the use of e-reverse auction use, and the chapter concludes with the possible future research areas and conclusion.

BACKGROUND

The empirical research on e-reverse auction reveals that the main reason to use e-reverse auction is to maximize the savings in the procurement of products or services. One of the popular service provider, Ariba StartSourcing indicates that they are delivering “value for organizations for all sizes and industries by- sourcing \$340 billion spend in annual across 500 categories, saving \$30 billion annually and cutting process and cycle times by 50-70 percent” (Ariba StartSourcing Solution, 2015).

In contrast to price decrease, switching to a new supplier may increase the transaction cost. The basic principle of Transaction Cost of Economics (TCE) is that “people like to conduct transactions in the most economical way” (Teo and Yu, 2005, p. 452). It explains the reason for selecting one transaction over another. In that transaction the costs are minimized and the benefits are maximized. With e-reverse auction, buyers may procure the products or services with less prices and search costs. Whereas, the supplier change may lead to an uncertainty, which is the principal factor of TCE (Teo and Yu, 2005). Mithas et al. (2008) define uncertainty in the element of non-contractible dimensions. Non-contractible dimensions include situations that cannot be estimated at the start of the contract. Task-based non-contractibility includes uncertainty about the quality, technological investment requirement and prosperity in information exchange, whereas interaction-based dimensions include responsiveness, trust and flexibility of the suppliers for the possible changes in the demand. They revealed that non-contractibility presents an obstacle in the decision to use e-reverse auction. To mitigate risks of the non-contractibility dimensions, buyer can identify a value for the cost

of vendor change. During the e-reverse auction, incumbent supplier loses the auction if the gap between the bids is higher than that pre-identified cost of supplier change factor.

The literature on reverse auction show that larger organizations, using Internet for businesses, also prefer to use e-reverse auction (Hartley et al., 2004; Mithas et al., 2008). IT capability is a prerequisite in order to determine to use such a system (Mithas et al., 2008). The characteristics of a purchased product or services also become important in the decision to use the system. Some products or services require investment in order to produce. These products are generally special products, in which description of such products require close coordination between the supplier and the buyer (Mithas et al., 2008; Schoenherr and Mabert, 2011).

In addition, use of e-reverse auction has negative effects on supplier-buyer relationship (Löscher and Lambert, 2007). Especially the behaviors and practices of buyer during auction may deteriorate the relationship. Furthermore, the lack of clarity in product specifications and requirements of contract create concern among suppliers (Tassabehji et al., 2006)

Our aim in this study is to understand the factors affecting e-reverse auction use. According to the Technology Acceptance Model (TAM), the final decision to use a system is determined by intention to use. Potential users first intend to use and then actually use the system. Therefore, behavioral intention to use is the immediate predictor of actual usages. Perceived usefulness and perceived ease of use are two important beliefs that explain usages and considered as the human related factors. TAM is taken as the base model in constructing the research model since the TAM is a widely used and robust model for predicting and explaining user behavior in IT usage (Davis, 1989; Legris et al., 2003). Several studies related with e-reverse auction also confirmed the significant effect of both perceived usefulness and perceived ease of use on usage (Gumussoy and Calisir, 2009; Gumussoy and Calisir, 2012).

Furthermore, subjective norms, which refer to the “person’s perception that most people who are important to him think that he should or should not perform the behavior in question” (Ajzen and Fishbein, 1980), is included as one of the social factors and potential predictors of system use.

As a result, the research model integrates the concept of buyer price, non-contractibility, organizational factors, product/service related factors, supplier related factors, subjective norms and TAM as the potential predictors of e-reverse auction use.

RESEARCH MODEL

The e-reverse auction usage model is presented in Figure 1.

Technology Acceptance Model

Davis (1989) developed TAM in order to understand the main reason for using an IT system. According to the TAM, potential users first decide to use a system and then actually use it. Therefore, it is expected that actual use is predicted by behavioral intention to use, which in turn positively affected by two beliefs: perceived usefulness and perceived ease of use. Perceived usefulness is defined as the “degree to which an individual believes that using a particular system would enhance his or her performance”, perceived ease of use is “the degree to which a person believes that using a particular system would be free of effort” (Davis, 1989, p. 195). According to the TAM, as the system becomes more useful and users do not spend too much effort, intention to use a system

Figure 1. E-reverse auction usage model

is affected positively. Furthermore, perceived ease of use influences behavioral intention to use indirectly through perceived usefulness. As the system becomes more complicated, users spend more time on how to use the system. This may induce users to stop using the system instead of spending too much time on how to use the system. The studies related with e-reverse auction also confirmed that TAM is applicable in explaining the use of e-reverse auction (Gumussoy and Calisir, 2009; Calisir and Gumussoy, 2012). Therefore, it is expected that the relationships defined in the TAM is also applicable in understanding e-reverse auction use.

Subjective Norms

Subjective norms refer to the “person’s perception that most people who are important to him think that he should or should not perform the behavior in question” (Ajzen and Fishbein, 1980). The buyer may decide to use e-reverse auction system with recommendation of other people (such as managers or colleagues) whose point of view are important. Several studies also confirmed the significant effect of subjective norms on the decision to use e-reverse auction (Gumussoy and Calisir, 2009; Calisir and Gumussoy, 2012). Gumussoy and Calisir (2009) found that the opinions of both peers and managers affect the decision to use e-reverse auction use. Calisir and Gumussoy (2012) also confirmed that subjective norms explain the use of e-reverse auction together with attitude and perceived behavioral control. Therefore, it is expected that subjective norms of buyer has a positive effect on behavioral intention to use e-reverse auction.

Buyer Price

Buyer price is influenced with the cost saving of e-reverse auction. Cost saving is “the difference between willingness-to-pay and actual price paid” (Cui and Lai, 2013, p.316). One of the main reasons for using e-reverse auction is the price decrease.

For example, in 2001, General Electric saved 600 million dollar by putting 12 billion dollar to contracts (Kwak, 2002). Davis (1989) revealed that when the saving with the use of e-reverse auction is high, users perceive that the system is more useful. Therefore, it is expected that the buyer who has good experience on the results of previous auction in terms of price decrease will intend to use e-reverse auction in the future.

Non-Contractibility

Non-contractible dimensions include uncertainty and cannot be predicted at the moment, but the changes in the environment and performance in the future may affect the cost of transaction. Mithas et al. (2008) divide non-contractibility dimensions into two: task based non-contractibility and interaction based non-contractibility. Task dimension helps to increase product performance while interaction dimension supports the long term relationship (Mithas et al., 2008). Task-based non-contractibility includes issues related with quality, technology investments and information exchange. Focusing only on purchasing prices may increase the long terms costs since a new low price supplier may have quality problems that cannot be taken into account at the beginning (Hartley et al., 2004). Although buyer may easily specify the requirements of quality, achievement of the standards may be much more difficult for the suppliers. Furthermore, an information exchange especially in terms of tacit knowledge becomes standard with the long term relationship developed between the partners (Mithas et al., 2008). Buyer company also may not be sure about the supplier’s capacity to fulfill the technological investment requirements in the future.

Interaction-based non-contractibility is related with the uncertainty about the relationships between the partners in the future. Buyer wants to trust to suppliers in terms of its integrity, benevolence and ability of supplier in the forthcoming experiences (Zhou, 2013). Integrity is the reliability of supplier in terms of maintaining commitment.

Benevolent suppliers do not only think the benefits of themselves but also the buyer organization. Perceived ability is the capability and adequacy of supplier in terms of knowledge and fulfilling the buyer organization's mandates (McKnight et al., 2002). Furthermore, buyer prefers suppliers who can respond to changes and have adequate flexibility (Mithas et al., 2008). Because this kind of trust is developed over time, buyers may prefer to work with the suppliers that they are certain about the trustworthiness. Therefore, it is hypothesized that the greater the non-contractibility, the less likely the buyer will benefit and use the system.

Organizational Factors

The studies related to the e-reverse auction revealed that organization size has an effect on the decision to use e-reverse auction. Larger firms generally have internet connection and adequate IT infrastructure that e-reverse auction system may be integrated. Furthermore, the volume of small size organizations' needs in terms of products and services may be minor to conduct e-reverse auction (Hartley et al., 2004). Similarly, Hartley et al. (2004) found that firm size is the strongest predictor of likelihood of e-reverse auction use.

Management prioritization and support for e-reverse auction usage are also critical. Some companies put the usage of e-reverse auctions in the employee yearly targets to increase the number of e-reverse auctions so that they save in procurement activities. Therefore, it is expected that managerial prioritization and support for e-reverse auction may increase the use of e-reverse auction.

Product/Service Related Factors

The importance of a product is related with the perceived impact of the product on the firm (McQuiston, 1989). Buyer may not decide on the supplier of high important products easily since the price competition conducted during e-reverse auction cannot be the sole determinant. The buyer

wants to be sure that the products can be procured in a secure way. This can only be achieved by traditional or face-to-face negotiations (Schoenherr and Mabert, 2011). In the literature, Schoenherr and Mabert (2007) show that the companies prefer to use system for more commodity-like product or services. Furthermore, the specialized products require more asset specificity. Asset specificity is the "particular physical or human capital investments that a firm expects to undertake in order to support a given stream of transactions" (Mithas et al., 2008, p. 708). Difference between the asset specificity and non-contractible dimensions is that asset specificity is the need of asset for current stable transactions, whereas non-contractible dimensions involve activities that may change between organizations over time (Mithas et al., 2008).

Product specification difficulty, which refers to the "amount of information needed to fully specify attributes, is sometimes referred to as description complexity" (Mithas et al., 2008, p. 710) may become important in the decision to use e-reverse auction. At the start of the auction, buyer prepares RFQ that describes the specifications of the product or services. On the other hand, there may be fewer suppliers that meet the specifications defined in the RFQ. This decreases the competition during e-reverse auction.

Several studies also confirmed the significant effect of purchase importance (Tassabehji, 2010), product specification difficulty (Schoenherr and Mabert, 2011) and asset specificity (Mithas et al., 2008) on the use of e-reverse auction. Therefore, it is expected that the greater the purchase importance, product specification difficulty and asset specificity, the less likely that the buyers will use e-reverse auction.

Supplier Related Factors

E-reverse auction can only be conducted only when both partners- buyer and suppliers agree to use such a system. In an e-auction system, buyer examines the potential suppliers that the products

can be procured and sends RFQ to join the auction. The lack of supplier may impact the effective use of e-reverse auction negatively because a competitive environment can be settled down only if there exists enough number of suppliers competing to each other. On the other hand, there may be barriers of suppliers in accepting request. The lack of knowledge on how to use e-reverse auction and security of all partners' information may be an obstacle to use e-reverse auction. There needs to make training programs on how to use the system. Furthermore, the information of the parties may be secured with a contract. In addition, the literature on e-reverse auction emphasize that e-auctions affect supplier relationships negatively (Hartley et al., 2006; Gattiker et al., 2007; Tassabehji et al., 2006). Especially, the non-ethical behavior of both supplier and buyer may deteriorate the relationship (Tassabehji et al., 2006). Therefore, lack of e-reverse auction knowledge and available suppliers, deterioration of supplier-buyer relationship and information security concerns may have negative effects on e-reverse auction use.

FUTURE RESEARCH DIRECTIONS

The current study offer a comprehensive research model that explains the possible reasons for using e-reverse auction. By collecting data from the actual users of e-reverse auction, this model may be used to reveal the significant factors affecting e-reverse auction usage decision. Furthermore, group differences in terms of sector or culture can be explored by collecting data from different groups. On the other hand, a successful e-reverse auction can be achieved if both parties- suppliers and buyer organization benefit from the system. As a further study, a research model that explains the reasons of use from the perspective of suppliers can be developed.

In the research model, it is hypothesized that buyer price is one of the important motivator of using e-reverse auction. As a future study, the factors affecting buyer price may be analyzed. According to the studies related to this topic revealed that

different auction configurations may yield different results (Carter and Stevens, 2007; Mithas and Jones, 2007). Carter and Stevens (2007) examine how different reverse auction configurations affect the bid price and supplier's perception. Mithas and Jones (2007) analyze more than 700 auctions conducted in the automotive industry and analyze the effects of bidding competition, information asymmetry, reserve prices, bid decrement and auction duration on buyer surplus.

CONCLUSION

The rapid developments in IT enables the procurement of products or services via electronic system. Buyer organizations use e-auction system to achieve a more competitive environment which leads to great price reductions. Although e-reverse auction system provides benefits in terms of price decrease, small cycle times to determine the prices of products or services compared to standard procurement systems, it includes some risks that may decrease the use of e-reverse auction. In the current study, an integrated model, which includes both the benefits and risks of using e-reverse auction in addition to TAM, is developed. The developed model can guide e-reverse auction users and the procurement managers of the organizations to generalize the use of e-reverse auction.

KEY TERMS AND DEFINITIONS

Acceptance: A decision to use a particular IT/IS system.

Bidding: It is an offer of a supplier during e-reverse auction that the supplier is willing to sell.

E-Procurement: Purchase of a product or a service over internet.

E-Reverse Auction: It is a type of e-auction, conducted in real time over internet between buyer and suppliers in order to determine the supplier and the price of a product/service.

Negotiation: It is a discussion about an issue to reach a consensus between the parties.

Request for Quotation: Includes the specifications and some critical contract terms like payment terms etc. of a product or a service to be auctioned, and is prepared by the buyer in order to make an invitation to the suppliers.

Reserve Prices: It is the starting price of an e-reverse auction determined by a buyer with the examination of historical prices of a product/service.

Advanced ICT Methodologies (AIM) in the Construction Industry

B**M. Reza Hosseini***Deakin University, Australia***Saeed Banihashemi***University of Technology Sydney, Australia***Fahimeh Zaeri***Auckland University of Technology, New Zealand***Alireza Adibfar***University of Florida, USA*

INTRODUCTION

A wide range of advanced ICT methodologies (AIM) have made inroads in the construction market due to the conditions rampant in today's business environment. That is, the trend of globalisation, the fierce competition in the market and the need to deliver more complex projects have led leading construction companies towards adopting available technological innovations (Toole, Hallowell, & Chinowsky, 2013). As a corollary, the construction community has observed a rapid emergence of different AIM to improve communications, visualization, and foster collaboration among the parties involved in construction projects. Nevertheless, the overall rate of adoption within the industry has been slow, particularly in small and medium sized (SMEs) companies (Heydarian et al., 2015). Evidence shows that such slow uptake of cutting-edge methodologies is for the most part stemmed from a lack of support of practitioners in the construction industry exacerbated by clients being uninformed of the advantages of available methods for their projects (Cao, Li, & Wang, 2014). In essence, major barriers to widespread adoption of new technology in the construction industry have roots in lack of familiarity of clients, managers and company directors

with AIM, and the potential benefits envisaged for utilizing such technology as observed by Van der Vlist, Vrolijk, and Dewulf (2014). As asserted by Williams (2007, p. 6) one barrier to adoption of AIM is "Lack of knowledge by people in the construction industry about what is possible."
